The possibility that strychnine given hypodermically might be of value in treating asthma, was first suggested to me by the good results which were obtained by Dr. Echeverria in the treatment of epilepsy with this alkaloid. Asthma is closely allied to the latter disease, and that which benefits the one should also benefit the other—at least on theoretical grounds. I have been using strychnine daily in treating asthma during the last six months, and I believe with more prompt and more definite results than can be obtained with any other drug. My earlier cases were all treated with strychnine alone ; but from a varied experience, I think that the addition of atropine enhances its action somewhat : at least in old and stubborn cases. Below appear the histories of some of the cases which were treated with these agents. The first three were treated with strychnine alone, and the last three with strychnine and atropine.

I begin with one-fiftieth of a grain of strychnine, and one-one hundred and fiftieth of a grain of atropine daily, gradually increasing the strychnine to one-twenty-fifth or one-twentieth of a grain, and the atropine to one-one hundredth of a grain. After a thorough impression is made on the disease, the drugs are administered every other day, and as the patient improves are gradually abandoned. While some cases get well under this treatment alone, in others necessity demands that the influence of these agents be fortified by efforts which seek to control the causes of the attack, as well as by measures which help to build up and fortify the general system.

Case 1. Male, aged 25, first seen October 12, 1889. For some time he had had a constant cough and nightly attacks of shortness of breath. The attacks came on suddenly about midnight, and subsided in a few hours. He had sibilant and mucous râles over the whole chest. I administered one-fiftieth of a grain of strychnine hypodermically. He had no attack the following night, and slept well. The cough also improved. He received daily injections of the same dose for three days. Afterwards this was increased to one-twenty-fifth of a grain every other day. By October 24 the physical signs had all disappeared, and the man was discharged. He received nothing but strychnine.

Case 2. Female, aged 30, consulted me November, 1889. She had had occasional attacks of asthma since girlhood. Five years ago her ovaries were removed, and since that time her asthma is decidedly worse, recurring nearly every night at the present time. She also coughs and expectorates a good deal. Very little physical evidence of disease was found in her lungs. She was placed on strychnine injections, at first every day and in doses sufficient to impress the system. Her attacks gradually diminished, and she had no return of them for six weeks, after which she failed to report. In addition to the strychnine she received cod-liver oil and phenacetine, the latter in four-grain doses three and four times a day.

Case 3. Male, aged 30, came under observation December 1, 1889. He had suffered from asthmatic bronchitis for a number of years. The attacks of asthma appear nightly and are preceded by cough and expectoration. He is compelled to sit up for several hours during every paroxysm. The

cough sound simulates that of pertussis. The patient is losing flesh. There is no dulness, but his lungs abound in fine râles towards the base of the chest. The strychnine injections relieved the cough, and shortened the duration of the dyspnœa in a very short time. In the course of four weeks he considered himself well, although there were still some râles at the base. Besides the strychnine he received quinine, iron and ammonia.

Case 4. Male, aged 31, plasterer, first seen November 14, 1889, when he gave the following history: Cough for five or six years, yellow expectoration and sudden attacks of shortness of breath, which usually come on about 3 or 4 o'clock in the morning and sometimes continue for two or three days, and which during last year became more marked than before. Is unable to follow his vocation. No dulness. Sibilant and mucous râles over the whole chest. He received one-thirty-third of a grain of strychnine and one-two-hundredth of a grain of atropine hypodermically. November 20, dyspnœa on exertion improved; has had no attack of asthma since the first injection; says he feels better than he has for the last two months. Before he received the injections he was compelled to inhale the fumes of a "patent remedy" every morning before he was able to rise; this is no longer necessary. The injections were continued nearly every day until November 30, when he felt able to go to work. Was seen December 19. He has been at work ever since, and, with the exception of two slight attacks, he has had no return of asthma. I prescribed hypophosphites and no more injections. March 14, 1890, he reports that he has had no asthma since December last. He sleeps well, his cough is slight, and he is able to follow his trade during the winter season for the first time in two years. Chest clear of râles excepting a few at the base.

Case 5. Male, aged 37, had asthma since he was a child. His father died a drunkard, and the patient is addicted to alcoholic excess. October 17, 1889, he received one-fiftieth of a grain of strychnine about every other day until November 16, with but slight amelioration in his condition. On this date he received strychnine, one-twenty-fifth of a grain, and atropine one-one-hundredth of a grain. After this time the attacks abated somewhat, and in the next six weeks he had but one slight attack. He occasionally drank too much liquor while under treatment. At this period I lost sight of him and am unable to say how he is at present.

Case 6. Male, aged 51, clerk, was first seen December 2, 1889. He had had asthma for thirty years and daily attacks during the last ten years. Cough and dyspnœa were constant. Has been unable to lie down to sleep for eight years, but spends nearly all his time sitting with his elbows propped on the arms of his chair. The only relief he has is from smoking "Jamestown weed." His appetite is good, his bowels are irregular and his stools are changeable in color. He passes about half a pint of urine in twenty-four hours. He has itching over the whole body. He has much distress in the præcordia, and dropsy of the abdomen, scrotum and legs. His legs and abdomen are swollen so much that he is unable to wear his former-sized trousers, and the dropsical serum oozes so copiously through the skin below the knees that his drawers and socks become thoroughly saturated and have to be changed two or three times each day. He has no dulness over the lungs, but marked blowing inspiration in the apex of the right lung. Large and fine mucous and sibilant râles abound over the whole chest. There is about one-tenth, by bulk, of albumin in his urine. His weight is 108 pounds. His mother and a brother died of asthma. Strychnine and atropine were given, at first daily, afterwards every other day. To relieve the dropsical effusion and constipation, concentrated doses of magnesium sulphate were alternated every other evening with doses of sodium phosphate. He also received seven and a half grains of antipyrin, one grain powdered digitalis leaves, and one grain quinine, every four hours. On December 13, the albumin had entirely disappeared from the urine and the dropsy was very much improved. The man passed two pints of urine and his stools were normal in color. December 24, he had had no asthma since treatment began, and was able to lie down and sleep a whole night without waking. He was taking the antipyrin, digitalis and quinine only three times a day. He now began taking cod-liver oil. January 17, 1890, he felt very well. The abnormal physical signs had all disappeared from his chest and there was not a trace of dropsy. *March* 18, 1890, he had had no asthma since he was under observation. His weight was 114½ pounds.

Experience with the hypodermic use of

these drugs in a number of other cases of asthma which I have under observation at the present time convinces me that they are a valuable addition to the armamentarium of asthmatic therapeutics. Not only have I used these agents in asthma, but I have also found them useful in treating other forms of cough and dyspnœa.

Reports of Clinics.

PENNSYLVANIA HOSPITAL SURGICAL CLINIC.

DR. JOHN ASHHURST, JR.

Lacerated Wound of Foot. Traumatic Fever.

The patient was a boy, eight years old, who had been run over by a cart on the day before. There was a lacerated wound of the sole of the foot, about two inches in length, and another of the dorsum, about three and a half inches long. This was associated with an extensive crushing of the tarsus and metatarsus. Part of the bones were removed on admission, and a drainage-tube was inserted from the upper to the lower wound. A few stitches were inserted. The child rapidly developed a high fever—up to 103°, with delirium and spasmodic twitchings of both arms and legs. There was no locking of the jaws, or opisthotonos. The stitches were removed to reduce the tension upon the parts. A dose of five minims of the deodorized tincture of opium was given and repeated once, and one-tenth of a grain of morphia was twice injected hypodermically, the last injection giving the patient four hours sleep. He was given a saline diaphoretic—citrate of potassium with sweet spirits of nitre; and an ice-bag was applied to his head. The limb was wrapped in lint, wet with a mixture of equal parts of alcohol and of a 1 : 2000 bichloride solution. The wound was irrigated with a 1 : 3000 bichloride solution, and was allowed to gape widely. Under this treatment the fever abated rapidly, and the wound presented a healthy appearance.

Cicatricial Deformity of the Hand.

The next patient was a young woman who had had both hands caught between hot rollers, resulting in a burning and crushing wound. These healed with marked deformity. She returned to the hospital some time afterwards, because of the deformity and loss of power in both hands. The fingers had grown together, and Dr. Packard operated upon the left hand with considerable success, and upon the right hand without attaining the same degree of success. She had now come back for further relief.

Dr. Ashhurst removed the ring and middle finger, which were useless, and took from them a flap to cover the surface of the palm, where the tension of the cicatrix had prevented healing. The operation was a tentative one, and was undertaken in the hope of securing a fairly useful hand.

Mammary Abscess in the Male.

This is a rare condition in the male. No history of injury to the gland was given. The abscess was below the nipple, in the lower portion of the gland, and had lasted about eight days. The size most abscesses attain in the male is much less than in the female, because of the rudimentary condition of the gland. The treatment is the same. An incision was made in a line radiating from the nipple to the circumference, thus avoiding a division of the lacteal ducts which in the female might result in a lacteal fistula. The evacuation of pus was assisted by gentle pressure with a wet sponge. A poultice was applied next. After the discharge ceased, strapping by adhesive plaster would be resorted to.

Hemorrhoids and Fistulæ. Stricture of Rectum.

A colored man was the next patient. He had been operated upon before for fistulæ. The condition was found to be due to a malignant stricture of the rectum. The sinuous tracks were slit up, and the redundant portions of flesh were removed, to secure a more open wound. The tracks were also scraped.

Stricture of the rectum was described as malignant and non-malignant. The non-malignant variety, Dr. Ashhurst said, could be relieved by the use of bougies. Malignant disease of the rectum does not, as a rule, produce occlusion of the bowel. If it should, colotomy ought to be performed.

CHOLERA IN ASIA.—The Russian Government has sent Dr. Avedik Babajew, who is the head of the Sanitary Department at Tiflis, to Persia, to report on the cholera in that country.

FOREIGN CORRESPONDENCE.

LETTER FROM BERLIN.

BERLIN, February 7, 1890.

Typhoid Fever Bacilli in the Urine.—Phenacetin as an Anti-rheumatic.—Sub-benzoate of Bismuth, a substitute for Iodoform.—The Berlin pseudo-hermaphrodite.—Absence of Vagina and Uterus.

A decade or so ago when visiting the renowned Dr. Aufrecht, Chief of the Magdeburg City Hospital, my attention was for the first time directed to the examination of urine for typhoid fever bacilli. It must be admitted that aside from the mere scientific and pathological aspect, the determination of these specific microbes has also an important diagnostic value. Dr. Neumann, of Berlin, read an interesting essay recently, before the Berliner Medicinische Gesellschaft on this subject. He had made 114 single observations, in 11 of which the specific typhoid fever bacilli were discovered. Neumann's method recommends itself for its simplicity particularly. He sterilizes the reagent-glass and catheter over an alcohol-lamp, cleanses the orifice of the urethra with antiseptic cotton and obtains a suitable material for observation by allowing the first part of the urine to drain off. A drop of urine being now placed under the microscope, the field of vision will be found teeming with mobile bacilli. The healthy bladder does not contain any bacilli, hence we can *a priori* diagnose the microbes found as typhoid fever bacilli. In order, however, to determine, indubitably, the nature of these microbes, special bacteriological examinations, and pure cultures on various soils are indispensable. The question of how these bacilli find their way into the urine, Dr. Neumann answers in a very satisfactory manner. During the typhoid process numerous bacillary foci are formed in the kidneys, and a reactive inflammation sets in around the renal capillaries in which the tubuli uriniferi also partake ultimately. It is to be noted, however, that these bacillary foci in the kidneys do not form constantly nor even very frequently during the typhoid fever process. This, no doubt, accounts for the comparative rarity of cases where the bacilli can be discovered in the urine. As the bacilli appear in the urine simultaneously with the roseola of the skin, the urine need not be examined previous to that stage. To be sure we must not confound the appearance of bacillary foci in the kidneys with circumscript parenchymatous nephritis setting in during the typhoid process, for in all his observations Neumann has never found any albumin in the urine. The bacilli find in the bladder an excellent soil for propagation, and exist in that organ after the kidneys have long ceased to transmit any bacilli to the urine. They have been found in the bladder as long as the twenty-first day of the fever. The question now arises, how does the last of the bacilli get out of the bladder? Neumann says the last bacillus swims away before it has time to propagate itself, hence the cause of disappearance is a mere mechanical one.

There is a great difference of opinion regarding the virtues of a drug as emanating from a well-known and conscientious clinician, and as coming from the manufacturing chemist or the discoverer. The quick and energetic way in which Professor Leibreich and others recently sat down upon somnal and its discoverer, Dr. Radlauer, proprietor of the Berlin Kronen-Apotheke, will, it is to be hoped, prove an effective check to all further inventive aspirations of German chemists. Much more acceptable is the discovery of new remedial virtues in an established drug such as the announcement of Dr. Collischon, of the Heilige Geist Hospital, Frankfurt on the Main, that phenacetin is an excellent anti-rheumatic remedy. It resembles salicylic acid, in that it develops its high remedial virtues only if given in large doses. The proper dose in which phenacetin acts reliably is twelve grains given four times daily or thirty grains given twice a day, morning and evening. After the pain has disappeared, it is advisable to continue the drug in small doses. Collischon is rather emphatic in declaring that one to two ounces of the drug during one to three weeks will cure any case of acute articular rheumatism. In the majority of cases treated by Dr. Collischon, it was only exceptionally necessary to resort to salicylic acid. The well-known unpleasant secondary effects of salicylic acid, naturally invite the trial of other anti-rheumatic agents, although upon antipyrin and salol but little praise can be bestowed. Collischon himself, suffering from musculo-articular rheumatism, took nearly four ounces of salol in three weeks without the slightest beneficial result, while 30 grains of phenacetin, taken twice a day, promptly relieved Dr. Col-

lischon in two days. The drug is well borne as a rule. In a few cases only considerable perspiration, although without subsequent weakness and cyanosis, ensued after 15-grain doses given four times. The temperature usually sinks on the second or third day to one-half or one degree (Centigrade) below normal; the pulse falls 10 to 15 beats and respiration also becomes slower. An exanthematous eruption has never been observed. The acute clinical forms of articular rheumatism yield best to the drug; less easily the non-febrile forms, and not at all the muscular forms. The patients on whom Dr. Collischon's observations have been made were all well nourished and had comparatively strong constitutions. Dr. Collischon advises that the use of the drug should at first be attended with some caution.

Dr. Finger recommends sub-benzoate of bismuth as a valuable substitute for iodoform in soft chancre. The drug is a white, fine powder, obtained by heating subnitrate of bismuth with hydrochloric acid. The advantages of iodoform in rapidly cleaning and healing the wound are also obtained from sub-benzoate of bismuth which, besides, has the great advantage of being absolutely odorless.

An interesting case of a masculine pseudo-hermaphrodite was recently presented before the Berlin Medical Society by Dr. Rosenthal. The patient, a young man 23 years of age, was at birth regarded as a girl and received the name of *Sophie*. A little difficulty in passing water was noted on the third day after birth, and a trivial operation performed. The patient grew up, but experienced considerable difficulties during his school days by being expelled from various institutions for improper behavior. At the age of 12, the patient of his own accord asked to be examined by a police surgeon. At the examination the patient was pronounced to be of male sex and the authorities conferred the name of Hermann upon him. His sexual desires awoke early, having seminal emissions when thirteen years old. The patient's voice is manly, he has a little moustache, but a small figure, and a womanly complexion and expression of the face. The genitals present, at first sight, a decidedly female aspect, are covered by hair, and present two prominences similar to the two labia majora. A closer inspection, however, demonstrates that we have to deal here with a divided scrotum, the right portion of which contains an intestinal loop and the left of which is empty. Testicles are absent, hence it is a case of double cryptorchism. Between the two scrotal portions the penis is located, small, moderately developed, two and one-half inches long. The copus cavernosum is normal but the prepuce is absent. From the skin of the penis just behind the gland apparently two labia minora arise. The penis is fixed in a backward and downward direction in a manner which causes during urination the wetting of anus and thighs. A rectal examination reveals also the presence of a small prostatic gland. The patient cohabits in a sitting attitude, though of course an immissio penis is out of question.

Dr. Aleksa described a case with congenitally absent vagina and uterus occurring in woman 26 years of age, married since eight years. The woman sought medical advice for her sterility. Examination revealed both large and small labia in a normal development and between them a funnel-like opening which the physician regarded at first as an unruptured but greatly expanded hymen. A small incision 2–3 m. m. deep not opening the vagina, the suspicion of the absence of this organ was first awakened. The following examination proved that both vagina and uterus were absent. Patient admitted having intense sexual appetite, but having never received any satisfaction from cohabitation, but that on the contrary she had often fainted and had been ill for some days after the act.

This morning a young New York physician and a German medical student fought a pistol duel in the Grünewald, near Berlin, the cause being a love affair—the daughter of the mutual boarding-house keeper. The German student was shot in the left thigh; and as the police surprised the duelists, an unwelcome consequence is likely to follow.

Tooth Washes.—Liquid dentifrices are not usually so detersive or cleansing as pastes or powders, and are better suited for remedies for the breath or for the purpose of applying a preparation to the gums than for cleansing the teeth. Where they are expected to have a cleansing effect, it is usually obtained from soap. Myrrh and astringents can be readily applied to the gums in this form of dentifrice, and also a perfume, serving the same purpose as the various cachous of the market, can be employed. This latter class of dentifrices belong more strictly in the sphere of the perfumer.

PERISCOPE.

Treatment of Undescended Testicle.

Mr. W. Watson Cheyne, Surgeon to King's College Hospital, London, has an interesting paper in the *British Medical Journal*, Feb. 15, 1890, in which he says that, on account of the grave inconveniences which attend the retention of testicles in the inguinal canal, he has, like a good many other surgeons, made attempts in several cases to bring them down to their proper position in the scrotum, but he cannot say that the results of these attempts have been very brilliant. He says he has tried most of the plans suggested, and has in all cases, after freeing the cord and testicle, stitched the latter to the lowest part of the scrotum by means of catgut, and afterwards placed catgut sutures in the external ring to prevent the testicle slipping up again into the inguinal canal. The immediate result is that as soon as the hold on the testicle is relaxed, it retracts to the external ring, drawing in the scrotum with it, thus forming a pucker, and the ultimate result is that the testicle lies at, or very little below, the external ring, in a position very little better than that which it formerly occupied. It struck him, however, if he could keep up the tension on the cord for some days it would gradually stretch, and that then, when the tension was relaxed, the testicle would remain in its new position in the scrotum.

A drawing illustrating Mr. Cheyne's article shows the mode in which this object was attained in a case which he describes.

He had a small triangular wire frame constructed which fitted into the perineum and over the pubes, and was kept in its place by threads of carbolized silk, attached to each angle of the frame and passed round the abdomen and thighs. At a point opposite the apex of the scrotum a projecting bar was attached to the frame to which the thread which passed through the cord could be tied. The mode of operation in this case was as follows: The testicle and cord were freed and brought down into the scrotum, in which a pouch was formed for its reception. A strong catgut stitch was then passed through the structures of the cord immediately above the testicle, and both ends were brought out through a hole at the apex of the scrotum and tied round the projecting bar. Care was taken that the vas deferens should not be on the side of the cord through which the thread might cut its way. In this way any desired amount of tension can be kept up on the cord, and in this particular case Mr. Cheyne did not stretch the cord at the time of the operation as completely as he intended ultimately to do but tightened it at the second dressing some days later. After stitching up the external ring and the wound, the whole arrangement was enveloped in antiseptic dressings. He did not, in this case, pass the stitch through the apex of the testicle but through the cord, because he did not wish to set up orchitis, nor to destroy any of the testicular structure, while he thought the stitch would not cut through the cord so quickly as through the testicle.

Of course it is only in a certain proportion of these cases that any operation with the view of bringing down the testicle can be of benefit, and I should only attempt it in cases where the testicle was fairly movable in the inguinal canal and could be readily made to protrude at the external ring. Where the testicle is retained at the upper part of the inguinal canal, the cord very short and the testicle much atrophied, Mr. Cheyne believes it is best, in view of the serious trouble to which it may afterwards give rise, to excise it at once and bring together the walls of the inguinal canal. The case he describes was that of a boy eleven years old, with both testicles in the inguinal rings, in which the old method failed on one side, and the new one succeeded on the other.

Signs of Death by Hanging.

In a paper on the Recent Progress in Legal Medicine in the Boston *Medical and Surgical Journal*, February 27, 1890, Dr. F. W. Draper, Professor of Legal Medicine in Harvard University, says:

At the International Congress of Legal Medicine at Paris, the physiology and pathological anatomy of death by suspension was the subject of an animated discussion. Coutagne showed the importance of differentiating the phenomena and appearances which follow compression of the trachea from those which result from compression of either the blood-vessels or the pneumogastric nerves. When one dissects out the nerves and isolates them, in the neck of a dog, and passes a cord tightly around the animal's neck be-

neath them, death is much more slowly brought about than in the cases in which the nerves are also included in the compression. With reference to the anatomical appearances, Coutagne insisted on the value of a comprehensive study of all the lesions and data in enabling the examiner to reach a correct diagnosis of death by hanging; the external inspection is particularly important. Sub-pleural ecchymoses have lost much of the significance which Tardieu attributed to them as diagnostic aids. The lungs are swollen, but they are not the seat of a true hyperemia, but rather of a special change to which Lacassagne has given the name "l'œdème carminé." The abdominal organs are sometimes congested to such a degree as to suggest poisoning as the cause. Coutagne did not believe that there was any single sign which, taken alone, was pathognomonic of death by hanging; although in strangulation the ecchymoses observed were generally less circumscribed than those in death by suspension.

Richardière declared that he found it impossible, by the anatomical appearances only, to diagnosticate a death by hanging from a death by strangulation with a cord.

Vibert recalled Hofmann's observation that one may find all the lesions of strangulation on the dead body of one who has not been strangled at all, but who has fallen from a height and received fatal injuries in that way.

Brouardel stated his belief in the impracticability of discriminating death by hanging from death by strangulation with a cord; and asserted that both topics should be studied together as being essentially identical. He did not think that the sub-pleural ecchymoses had a purely mechanical origin, but he was unable to formulate any satisfactory explanation of their development. Concerning the erotic sensations formerly believed to be regularly attendant upon a death by hanging, Brouardel declared that nothing of the kind occurs. If sometimes there is a discharge of seminal fluid in these cases, it occurs in from fifteen to twenty minutes after the death, and is due to cadaveric rigidity manifesting itself in the seminal vesicles. Besides, among those who have been resuscitated after suspension, not one has been known to testify to voluptuous sensations as a part of the proceeding.

Gosse related some experiments which he had made upon himself with reference to the phenomena of death by hanging. On two occasions he had carried the suspension to the point of losing his consciousness. He found that in these cases the cord did not compress the neck so as to prevent respiration. When the cord pressed forcibly on the carotids there was not much pain, but a buzzing sound in the head and an early onset of unconsciousness. If the rope pressed directly in front of the neck, over the trachea, the struggle for breath was very distressing. When the lungs are filled with air just before the noose is tightened, the suffering is lessened. The sub-pleural ecchymoses, also, have been found to be less numerous and less distinct when the lungs are fully inflated at the moment of the suspension.

Supra-pubic Cystotomy.

Dr. Albert Vander Veer, of Albany, reports, in the *Medical News*, March 1, 1890, four cases of subra-pubic cystotomy, and comments on them as follows:

While my experience with supra-pubic cystotomy is not so great to make a personal generalization valuable, yet I feel that a comparison of it with other operations, done by me for similar conditions, might not be amiss. First, I am sure that I am able to explore more thoroughly by the supra-pubic than by the perineal incision. More especially is this true where the patient is fat and has a deep perineum. My first case of supra-pubic cystotomy here reported was for the removal of a papillomatous growth. I had already operated in the case by the perineal method recommended until recently by Sir Henry Thompson. The subsequent history showed that the second operation was much more successful than the first. The facility with which the operation was done the second time thus showed a great improvement over the first. The growth was more accessible, the hemorrhage more easily controlled, and by the Trendelenberg position, with the use of the electric light and suitable retractors, an inspection of the field of operation was possible. Drainage was satisfactory. In the case of tuberculosis of the bladder, the diagnosis was surrounded by great difficulties. At that time there were no tubercular deposits in the mesentery, testicles or epididymis. Primary tubercle of the bladder is exceedingly rare. In this case the exploration was necessary to complete diagnosis. I am convinced that the same principles that are involved in the exploration

of other organs should be applied to the exploration of the bladder. Again, the experience of surgeons with tuberculosis of the peritoneum has been very satisfactory. Guyon reported two cases of tubercular cystitis treated by supra-pubic cystotomy and the application of iodoform oil to the ulcer. One case was cured two and a half years later. The other was improved, and there was an absence of tuberculosis in both after-treatment. From analogy, quite as much of the improvement can be attributed to drainage as to iodoform oil.

The two cases of stone were both accompanied by a severe type of cystitis, and one by prostatic hypertrophy, multiple calculi, and sacculated bladder. Litholapaxy is, in my opinion, absolutely contra-indicated in such cases. Permanent lithotomy has often been done, and calculi lying in sacs near the fundus have been overlooked. I have had so unfortunate an experience. Then, again, I have succeeded better with supra-pubic siphon drainage than with perineal drainage. It is very difficult to maintain an opening through the perineum after median section. Patients tolerate drainage-tubes badly, and their removal is often necessary after a few hours. After median lithotomy, patients begin to pass urine by the urethra often by the third day.

I had a case, not long since, of cystitis from enlarged prostate, in which the perineal section was done for drainage; a day after the operation the drainage-tube, which was a large one, slipped from the wound, and retention of urine occurred. A good deal more distress was caused in introducing it again, than in the same procedure by supra-pubic incision.

Forceps not in the Abdomen.

The *Pittsburgh Medical Review*, March, 1890, states that for two months a paragraph has been floating on the current of American journalism to the effect that two prominent surgeons of Pittsburgh recently left a pair of forceps in the abdominal cavity of a woman after a laparotomy, and that a third surgeon had discovered and removed them. It seems a pity to spoil such an interesting and harmless anecdote, but truth compels us to say that the story is without any foundation. Its origin was probably in a sensational newspaper tale published in this city some time ago, and evolved entirely from the active imagination of a newspaper reporter.

A news item in regard to this matter appeared in the REPORTER, Dec. 15, 1889, quoted from a lay paper. We are glad to learn that the story was untrue.

Artificial Feeding of Infants.

In an interesting article on the feeding of infants, in the *Archives of Pediatrics*, December, 1889, Dr. Arthur V. Meigs says:

Improved modern methods of feeding, and the greater degree of success attained thereby, have made it proper to look upon the question of employing wet-nurses from a somewhat different stand-point from formerly. The results of artificial feeding used to be so bad that in all cases, if it was in any way possible, it was wrong not to obtain a wet-nurse. Now we may give much more weight to the consideration of the many risks run from the woman's being perhaps diseased or having an insufficient supply or bad quality of milk, and that they are so apt, in this country at least, to become discontented, and go away without previous notice, just at some critical period of the infant's life. The class of society from which wet-nurses are drawn is a very low one, for they are, as a general thing, either women from the lowest ranks of life, who have had illegitimate children or have been deserted by their husbands, and therefore the chance of their being diseased is very great; and, besides, they are generally of such a low order as to be difficult to manage. Upon the other hand must be set the facts, that in artificial feeding, if the food is impure or the various component parts are not present in the right proportions, the fault is ours, and the remedy is easily applied. If we have intelligent people to deal with, and have their full confidence, so that they will carry out implicitly the directions given them, infants may be hand-fed with great success, and in some instances with more success than from the employment of wet-nurses, though, of course, there is not now and probably never will be, found any artificial food which will be equal to that provided by nature when it can be had at its best.

The end to be striven for in order that more general success may be attained in the artificial feeding of infants is to diffuse more widely and to make common property of the

knowledge how small a proportion of caseine exists in human as compared with cow's milk, and that in addition to the dilution which is necessary to reduce the amount of this constituent we must use, in proper proportions, cream, sugar and lime-water.

Treatment of Colds.

In the *New York Medical Journal*, March 1, 1890, Dr. C. H. Stowell, of Washington, has an interesting article in which he recommends the following line of treatment: If the patient is seen early in the attack he should have at once a hot foot-bath and a bowl of hot lemonade. He should then be placed in bed and covered with blankets until copious perspiration is produced. If seen at a little later stage, and the fever seems excessive and the whole system affected, then there are two marked remedies at our command—aconite and belladonna. The tincture of aconite is best given in small doses, half a drop once every half-hour for a few hours, until its physiological action is apparent. If the discharge from the nose be thin, or if the throat be involved, then small and frequently repeated doses of the tincture of belladonna will give marked relief. A brisk cathartic is often indicated and generally very desirable.

In the beginning of the attack the nasal mucous membrane is likely to be dry and swollen, giving the sensation of the presence of a foreign body, causing sneezing and a sense of fullness. In this early stage the abortive treatment, already alluded to, can be relied upon, if local treatment be combined with it. Cocaine and antipyrine are almost specific for this trouble. They can be used as a spray in the strength of one per cent. of the former with four per cent. of the latter. Thus:

℞ Cocain hydrochlor . . . . gr. ivss.;
Antipyrin . . . . . gr. xviij;
Sodii bicarb. . . . . gr. v;
Aquæ . . . . . f℥j
M. Sig.: Nasal spray.

This should be sprayed thoroughly into the nares. The swollen membranes soon retract, and nasal respiration is free and easy. The spray should be repeated as often as the nares become occluded. If any nasal symptoms remain after the first twenty-four or thirty-six hours, it is better to substitute a spray with an oil for its base. Thus:

℞ Cocain hydrochlor . . . . . gr. ix;
Aquæ . . . . . f℥ ss.;
Ft. solutio et adde
Olei petrolei . . . . . ℥ j;
Olei eucalypti . . . . . gtt. vj;
Olei gaultheriæ . . . . . gtt. iij.
M. Sig.: Nasal spray. Shake thoroughly before using.

This spray can be used morning and night for a few days only, or until the acute catarrhal symptoms have disappeared.

As atomizers cost money, and as they can not be carried about readily, a powder may be substituted for both the above. Thus:

℞ Sodii bicarb . . . . . gr. ij;
Magnesiæ carb. (levis) . . . gr. iij;
Menthol . . . . . gr. j;
Cocain hydrochlor . . . . . gr. iv;
Sacch. lactis . . . . . ℥ jss.
M. Sig.: Use as snuff.

The most marked relief will follow the use of this powder, and a few applications will do much to abort the catarrhal attack. Its effects are immediate, highly agreeable to the patient, and continuous for a number of hours.

In the case of young children, where a powder or spray cannot be used to advantage, an ointment can be substituted. Thus:

℞ Cocaine hydrochlorate . . . . gr. ix;
Anhydrated lard, } . . . . āā ℥ ss.
Vaseline, }
M. Sig.: Ointment for the nose.

A small amount of this can be placed on the end of a feather and inserted into the nose.

A word concerning any objection that may be urged as to the use of cocaine in this manner. 1. The amount prescribed in each case is small; especially is this true of the powder. The prescription given above will last a patient for days—in fact, his acute catarrh will disappear before all the powder is used. 2. Neither the sprays nor the powder should be continued after the first few days of the attack. 3. They should not be prescribed for chronic catarrhal affections; for while it is true they give great relief in chronic hypertrophic conditions, yet the relief is but temporary, and their constant use may give most undesirable effects. 4. The physician should dispense his own powder, giving not over a drachm to each patient. If possible, he should dispense the sprays as well. By so doing he will retain the power to prevent any overuse or misuse of the drug.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

TRANSPLANTATION OF THE THYROID.

Professor Lannelongue has recently, as reported in the *Bulletin Médical*, March 9, 1890, carried into effect the suggestion of Professor Horsley in the *British Med. Journal*, Feb. 8, 1890, to transplant to the human body the thyroid gland of a sheep, in the hope that it would supply the want of the natural thyroid in cases of what is known as myxœdema, or *cachexia strumipriva*.

Lannelongue has actually made the experiment on a girl fourteen years old, who was a typical myxœdematous cretin, and under his care and that of Dr. Legroux in the Trousseau Hospital. He removed the thyroid gland of a young adult sheep, and implanted two-thirds of its left lobe in a pocket prepared below the right breast of the patient. The neck could not be utilized, on account of the presence of myxœdematous tumors. The operation was done aseptically, and as bloodlessly as possible. The dressing was first changed after eight days, and the wound was found to be perfectly healed.

What will become of the implanted gland tissue, it is too soon to say; and, equally, no reasonable expectation can be formed as to the effect upon the economy of such a procedure. The hopes founded upon theory justify the experiment; but it must be understood that it is an experiment only and nothing more. The result of some experiments conducted by Schiff and Eiselberg some years ago indicate that this method may have promise of real usefulness. It is as yet a sort of curiosity in surgery; but it may some day be much more.

MEDICAL EXAMINATION OF SUSPECTS.

The importance of correct notions in regard to the subject of medical examination of persons suspected of lapses from virtue or of legal offenses in connection with the generative function is the subject of an Editorial in the *Lancet*, February 22, 1890. The article is founded upon a recent paper by Mr. W. F. Lowndes, in the *Liverpool Medico-Chirurgical Journal*, and refers to his experience as a surgeon to the Liverpool police as giving authority to the warning he addresses to medical men with regard to examinations of women suspected of recent delivery, and concealment of birth or child murder, of domestic servants suspected of being pregnant, and of males in custody for alleged indecent assaults. Mr. Lowndes shows clearly that in England such examinations are illegal without the consent of the party examined, supporting his position by reference to cases that have been made actionable with disastrous results to the medical man, and citing the case of an unfortunate lady who, accused of child murder, committed suicide rather than submit to the

examination by two medical men who had been furnished with a Coroner's order for that purpose. The *Lancet*, in 1871, secured a legal opinion that a Coroner issuing such an order and the medical man acting under it would alike be liable to heavy damages in an action. A woman in custody cannot be examined, even on a magisterial order, without her full consent; neither magistrates, nor policemen, nor medical men may infringe on the rights of any person. Mr. Lowndes advises medical men to never examine any woman under any circumstances without having first obtained her consent in the presence of one or more reliable witnesses, and, if possible, in conjunction with some other practitioner.

If this rule were always followed, much trouble and loss would be saved to medical men, who err through ignorance of the law, and especially of the fact that not even a judicial order will justify examination of the generative organs without consent of the person examined. The same rule applies to the examination of the male, in cases of alleged rape or indecent assault; and Mr. Lowndes's rule of action in such cases, is to obtain the individual's free consent; notifying him that the result of the examination may be in his favor, or it may be against him, and asking: "Do you still consent?"

The conditions referred to are not peculiar to any one country; although the law in regard to the rights of individuals may vary somewhat; and it certainly seems worth while to call attention to what might some day lead to serious embarrassment on the part of an over-zealous or ill-informed physician. The danger would be very great in the case of forcible examination of a suspected man or woman; and nothing but demonstration of the suspected crime and conviction of the offender would serve to avert it, if he or she were informed of his or her legal rights, and were disposed to vindicate them.

Physicians may well be aware of these facts, and shape their conduct according to such prudent rules as Mr. Lowndes suggests, for their own safety, and no less in justice to individuals who may be innocent, and who, even if justly suspected, are often not without some claim to consideration.

PHYSICIANS AND JURY DUTY.

We see, by an editorial in the *National Druggist*, March 15, 1890, that physicians and druggists in Missouri are free from obligation to serve on juries. The law under which the exemption is claimed reads: "No person being a member of any volunteer fire company duly organized and ready for active service, no person employed in any paid fire department, nor in any State eleemosynary institution, and no person exercising the functions of clergyman, practitioner of medicine, attorney at law, clerk, or other officer of any court, ferry keeper, druggist, postmaster, overseer of roads, coroner, constable, miller, professor, or other teacher in any school or institution of learning, judge of a court of record, superintendent of county poor-house, or any person over the age of sixty-five years, shall be compelled to serve on any jury."

This would be a good law for any State, so far as physicians and druggists are concerned—and we have, as physicians, no concern now with others. In Pennsylvania physicians are not by law exempt from jury duty. It is not long since the Editor of the REPORTER was summoned for jury service, and had to go to Court in spite of his engagements as a physician. It is true that it would probably never be difficult for a physician to have himself excused from actual service as a juryman by the Court; but it might prove a great hardship to him and imperil the health or life of some of his patients if he were compelled only to appear and were then soon allowed to return to his medical duties.

As there are physicians in most State Legislatures, it would be well if some of them would take this matter up and secure

the enactment of laws exempting physicians from being summoned to serve on juries. In so doing we believe they would have the approval of all thinking men, whether physicians or not.

FOREIGN PHYSICIANS IN FRANCE.

In the REPORTER, Jan. 11, 1890, mention was made of the French Government refusing to grant permission to English medical men to practice in places resorted to by English in France, without having passed a French examination. This action was strongly resented by the English profession and severely criticised by the British medical press; and it now appears that the French Government has appointed a Commission to discuss the question of foreign physicians practicing in France. At a conference of this Commission, held March 10, M. Spuller, the Minister of Foreign Affairs, urged the necessity of allowing foreign physicians full permission to attend their fellow-countrymen at French health resorts, and also advocated the granting of licenses to foreigners in special branches of medicine.

We have heartily sympathized with our English brethren in France in their unfortunate and unjust position. That foreigners in any country should be denied the right of medical attendance from their own countrymen seems to strain the proper surveillance of medical practice a little too far, and certainly English physicians should not be singled out for peculiar restriction.

There are a number of American physicians in France who are now enjoying extensive practices, and—so far as we know—no such restrictions have been placed upon them. We sincerely hope that the Commission will take such a sensible view of the matter as does the Minister of Foreign Affairs, and that France will be soon open to practitioners from any country, who bear diplomas from reputable schools of medicine, especially if their intention is to practice only among their own countrymen. It would undoubtedly serve as a sort of check upon the large visitation of foreigners to France if it were understood that visitors to that country could not secure the services of physicians from their native lands in case of illness or accident; and this, we think, would not be to the interest of the French themselves.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

THE INTERNATIONAL MEDICAL ANNUAL AND PRACTITIONER'S INDEX FOR 1890. Edited by P. W. WILLIAMS, M. D., Secretary of Staff, assisted by a corps of thirty-six collaborators —European and American. 8vo, pp. 600. E. B. Treat, Publisher, 5 Cooper Union, New York. Price, $2.75.

This is the American edition of an English work which has some excellent features, and some very poor ones. It is of some use to have succinct expressions of opinion from men who are specialists in important departments of medical practice; but it is almost a fraud upon the reader to have long articles on such subjects as "thermo-therapeutics," which in style and illustration seem like mere advertisements of special establishments. Like most works of the kind the Annual is very uneven in literary and scientific quality; and unlike some, it is padded out with advertisements which are an insult to the intelligence and honesty of the medical profession. On the whole, we would say that we see little use for such a book, regarding only its failings and passing by its faults; while if we fix our attention on its faults, we think the honest critic must give it unqualified condemnation.

SYLLABUS OF THE OBSTETRICAL LECTURES IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF PENNSYLVANIA. BY RICHARD C. NORRIS, A. M., M. D., Demonstrator of Obstetrics, University of Pennsylvania. 8vo, pp. 154. Philadelphia: W. B. Saunders, 1890. Price, $2.00.

This is a very good condensation of the Lectures on Obstetrics given at the University of Pennsylvania. It will doubtless be of interest chiefly to the students of this school, and will afford them far more accurate and suggestive "notes" than it is possible for the individual student to take. It should meet with favor among those for whom it is intended.

ESSENTIALS OF GYNECOLOGY. Arranged in the Form of Questions and Answers Prepared especially for Students of Medicine. BY EDWIN B. CRAGIN, M. D., Attending Gynecologist to the Roosevelt Hospital, Out-Patient Dept. Saunder's Question Compends, No. X. 8vo, pp. 190. Philadelphia: W. B. Saunders, 1890. Price, $1.00.

This is a most excellent addition to this series of question compends, and, properly used, will be of great assistance to the student in preparing for exami-

nation. Dr Cragin is to be congratulated upon having produced in compact form the essentials of gynecology. The style is concise, and, at the same time, the sentences are well rounded. This renders the book far more easy to read than most compends, and adds distinctly to its value. In its binding and print, the book is uniform with the others of the series.

MEDICAL AND SURGICAL MEMOIRS: Containing on the Geographical Distribution, Causes, Nature, Relations and Treatment of Various Diseases. By JOSEPH JONES, M. D. Vol. III, parts I and II. 8vo, pp. 901. New Orleans, La.: Joseph Jones, M. D.

The third volume of this monument of patient labor and untiring zeal sustains the standing of the previous volumes. The present volume is in two parts and is a review of the history of Medicine and Surgery in America from 1880 to 1890. Besides 901 pages of text it contains several addresses, several chromolithographic plates, twenty-one maps and charts, twenty-two extensive and elaborate tables, and numerous engravings. The first part of the volume deals at length with epidemic yellow-fever, which Dr. Jones claims is neither indigenous to New Orleans, Louisiana or the Mississippi Valley; and, if rigid and effective quarantine measures be enforced, can be excluded from these places. The second part of the volume consists of monographs on Medical Education, Teratology, Nervous Diseases, Insanity, and other subjects of interest to the profession.

A POPULAR TREATISE ON THE WINDS: Comprising the General Motions of the Atmosphere, etc. By WILLIAM FERREL, M. A., Ph. D., late Professor and Assistant in the Signal Service, etc. Large 8vo, pp. viii, 505. New York: John Wiley & Sons, 1889.

It is hard to do justice to a book of this sort in the space which we can spare to a notice of it. It is little to say that it is a most elaborate work, containing the result of careful and thorough investigations in regard to the phenomena of the atmosphere and the principles which govern them. The conditions and movements of the atmosphere as a whole and in its parts are described with the most painstaking thoroughness. There seems to be no element bearing upon the subject of meteorology which the author has overlooked, and every one is discussed so minutely that it is hard to understand how the book can be called a "popular" treatise. It is rather a work for the most practiced and learned meteorologists, and from them alone can it expect judicious appreciation.

LITERARY NOTES.

—The Competition for Water Tower and Pumping Station Designs announced by *The Engineering and Building Record*, December 14, 1889, has been a handsome success. The time of the competition expired about March 1, with no less than one hundred and twelve designs received, fifty-six of each structure, and these with a degree of merit which all who have seen them pronounce remarkable.

The first prize of $100, was awarded to Elmer Grey, Milwaukee, Wis., and the second, of $75.00, to James C. Green, Brooklyn, N. Y.

CORRESPONDENCE.

Acetanilid—Antifebrin.

THE NOMENCLATURE OF ACETANILID.

TO THE EDITOR.

Sir: The views of Dr. Bashore, supplemented by your note in the REPORTER of March 22, will undoubtedly be indorsed by physicians who have thought much on the subject of the nomenclature of new drugs. I write to answer the implied query in your note as to the privity of a chemical product. I have had a considerable experience with acetanilid under both its names, and have always made minute observations of its action. Acetanilid made by either of several American firms is identical in action with the same substance made by the parties who own the copyright on the word "Antifebrin." Several American firms "protect their interests" by the practical copyright on their firm-name, and a certain make of quinine is bought as confidently for pure quinine as if it were under the copyrighted name "antimalarin." Certain makes of acetanilid can be as confidently used as being pure and true to label. But I find many physicians, who ought to know better, under the impression that acetanilid is a substitute for antifebrin.

Yours truly,

G. WALTER BARR, M. D.

Bridgeport, Ill.

Cremation.

TO THE EDITOR.

Sir: I am fully in accord with the remarks of the brother from Iowa, on the subject of cremation. While it is "a mere matter of feeling," there is a very general one against it, not only among the people, but also among the professions. The Christian sentiment, of the resurrection of the body, has something to do with it; but there is more of it than that. Who willingly consents to the mutilation of the body of a near friend, and who but a crank or a medical man cares to think of having his body mutilated after death? And is not burning worse? We follow as a mark of respect, the bodies of our loved ones to the grave; and we visit their resting places afterwards. A monument or a jar of bone-ashes has no such tender reminiscences. I have heard

many admirers of Dr. Gross express the feeling that his cremation seemed like a wilful desecration, that deprived them of the satisfaction of paying respect to his memory, by visiting his grave.

The country is wide enough for burials, and the hygienic objections are proved to be as baseless as the ghosts that were supposed to infest the graveyards.

Yours truly,
P. J. Farnsworth, M. D.
Clinton, Iowa.

To the Editor.

Sir: It may be you would like to have an opinion from a medical man way out here. I have read the articles in the Reporter regarding cremation. It is a subject that should and must be discussed, for the time is coming, my prognosis is, when it will be the mode after death. By the remarks of your correspondents, it would seem that sentiment is in control, whereas it should be solid, practical sense. I am heartily in favor of cremation, and after death my body will be disposed of in that manner.

Publish this or not, as you see fit; but yours is my favorite journal of the ten I take.

Yours truly,
E. C. Adams, M. D.
Watertown, Dak.

[We usually strike out of letters to be published the complimentary phrases which correspondents kindly insert in them; but in this case we relax our customary severity.—Ed. Reporter.]

Gonorrhœa.

To the Editor.

Sir: Noticing from time to time the expressions of the medical profession in regard to the treatment of gonorrhœa, and the difference of opinion in regard to the subject, I am led to report to you a method which I have tried in my practice and which, so far as I know, is original with me.

I was led to the idea by the treatment of cases of chronic endometritis, which I treated with iodoform suppositories with very good results, and the idea occurred to me to treat gonorrhœa in the same way. Accordingly I tried the method on the next case that presented itself.

Case. J. M., acute gonorrhœa; penis very much swollen and inflamed; very severe pain on micturition; discharge profuse and muco-purulent. I prescribed suppositories (pencils) of iodoform, each containing 3 grains: one to be inserted every eight hours, after urinating, and one just before going to bed. The patient was instructed to keep quiet for the first twenty-four hours.

The result was a total cessation of the discharge and the abatement of all other symptoms within forty-eight hours after the first use of the suppository.

I have also used the same treatment in several cases of chronic gonorrhœa and in every case recovery was much more rapid than with any other treatment I have ever used.

Yours truly,
J. W. Magill, M. D.
Fairport, N. Y.

Notes and Comments.

Prolapse of the Uterus at Term.

At a recent meeting of the Obstretrical Section of the Royal Academy of Medicine in Ireland, reported in the *Lancet*, Feb. 8, 1890, Dr. Kidd read notes on two cases of complete prolapse of the cervical zone of the uterus, preceding labor at full term. The first case occurred in a multipara with large, well-developed pelvis, and who had never previously suffered from prolapse. Dr. Kidd found on arrival a red or semi-purple mass protruding from the vagina, about three inches from the vulva. It was composed of the greatly-congested cervical zone of the uterus, dragging down with it the vaginal walls, and accompanied by strong voluntary bearing-down pains. He reduced this prolapse at the time, and it did not return while the patient was kept on the back with the pelvis raised until true labor supervened five days later. At this time the congestion had disappeared, and a living child was born after a very favorable labor. The second case occurred in a primipara, aged thirty-four, with a small pelvis, and differed in this respect, that there was no congestion of cervix, but the head descended, bringing with it the cervix. The os, quite rigid and only dilated to about the size of a crown piece, protruded from the vulva one inch or more. There was a large caput succedaneum, and four incisions—two anterior and two posterior—had to be made in the cervix to enable the short forceps to be applied.

She was delivered of a living female child. Dr. Kidd classifies prolapse of the cervix at full term into: first, those cases in which the congested cervix descends without true hypertrophy; second, those in which true hypertrophy has occurred; third, those in which, the os being rigid, the cervical zone is dragged down by the advancing head without any congestion; and, fourth, those rare cases in which pregnancy has been known to take place in a completely prolapsed uterus and go on to full term. Treatment may vary according to the case, but in all cases an endeavor should be made to return the prolapsed portion. If that be not feasible, the canal should be dilated with hydrostatic dilators, manual dilatation, or by incision, and delivery induced by forceps or cephalotripsy, supporting the perineum and vulva well, lest the lower segment be drawn through.

Paris Academy of Medicine and Tuberculosis.

Our readers may remember that a committee, appointed by the Tuberculosis Congress which met in Paris in the summer of 1888, and was referred to editorially in the REPORTER, Sept. 8, 1888, promulgated last year, a series of instructions respecting the prophylaxis of tuberculosis. As stated in the *Lancet*, Feb. 8, 1890, these instructions were widely circulated; and their promoters, desirous of obtaining the highest medical support (although the names of the members of the committee were those of eminent men), submitted the document to the Academy of Medicine in October. The Academy referred the question to a committee, which reported much on the lines of the original draft of instructions, with some abbreviations. The Academy has ever since been engaged in debating the subject, many eloquent speeches have been made, and whilst there has been in the main an agreement as to the contagiousness of tuberculosis, a serious difference of opinion has been shown with regard to the particular part to be played by the Academy in publishing its conclusions to the world; so that when in due course the debate came to a close it was found impossible to vote the report of the committee as it stood. Matters were almost approaching a deadlock, when M. Bergeron, the perpetual secretary, proposed a resolution embodying the point upon which there was almost general agreement—viz., that tuberculosis is contagious, and likely to be disseminated by the dust of dried sputa and tuberculous pus. That resolution was referred back to the committee, which, however, could not agree unanimously either to recommend its adoption or to advise the adoption of the original report. In the end the following resolution was passed with hardly any dissent, and the long and formal debate was followed by the promulgation by the Academy of a general statement, which leaves the matter almost in the position it was before the Congress on Tuberculosis directed attention to it. The resolution runs: "Tuberculosis is a parasitic and contagious disease. The microbic agent of the contagion especially resides in the dust produced by the dried sputa of phthisical subjects, and by the pus of tuberculous wounds. The safest measure for preventing contagion consists, therefore, in destroying these sputa and pus, before their desiccation, by means of boiling water or by fire. The parasite is also occasionally found in the milk of tuberculous cows; it is therefore prudent not to use any milk until it has been boiled."

Use of Drugs in Epilepsy.

In speaking of the treatment of epilepsy, the *Lancet*, Feb. 8, 1890, states that most physicians rely mostly on the administration of drugs. Those which for the last thirty years have maintained the first position in this respect are the bromides of potassium, sodium and ammonium. At the National Hospital for the Paralyzed and Epileptic, we understand that a ton and a quarter of these salts are annually consumed by in-patients and out-patients, in spite of the drawbacks—such as acne, wasting and general depression—which in some individuals attend their prolonged use. In consequence of these drawbacks, physicians and pharmacologists have long been seeking for some drug which should be free from the disadvantages of the bromides in general use, and yet have an equally powerful action in controlling fits. Recently observations have been made in France with antipyrin, antifebrin, osmic acid, bromide of nickel, chloride of gold and borax. The first four appear to be entirely ineffectual; but borax, an old remedy, seems to have succeeded where bromides were not tolerated. Most observers agree that the important points in

the treatment of epilepsy are continuity of treatment over a long period, attention to the general health and to the regular action of the bowels, and the avoidance or removal of any cause of mental or physical irritation.

Tar-water and Tolu in Hemorrhages.

Corneille Saint-Marc recommends the following in certain hemorrhages, notably in hemoptysis, epitaxis, metrorrhagias, etc.:

℞ Distilled tar-water . . . . . f℥j
Syrup of tolu . . . . . f℥ss
Essence of lemon . . . . . gtj
M. Sig.: Take in teaspoonful doses during the course of twenty-four hours.

—*National Druggist*, March 15, 1890.

Physician's License Revoked.

The Philadelphia *Ledger*, April 5, 1890, has a report from St. Paul, Minn., that the license of Dr. Theodore Dedolph, a graduate of the University of Berlin, in 1884, had been revoked by the State Medical Examining Board. It was charged that last October Drs. Frederick and Theodore Dedolph were called to reset the broken arm of a German manufacturer of St. Paul.

As the effect of the chloroform was passing off the patient struck at one of the physicians, and Dr. Theodore Dedolph hit him in the eye, permanently injuring his sight. The case was brought before the Board in March, some five months after the occurrence.

Both the doctors and their servant say that the patient inflicted the injury on himself, and the doctors claim that the case is one of malicious prosecution, and instigated by certain physicians of another school of medicine.

Medical Association of Georgia.

The annual meeting of the Medical Association of Georgia will be held in Brunswick April 16–18. Indications point to a successful and profitable session. It is several years since the Association has met in the southern part of the State, and it is hoped that a general interest in the work of the Association may be awakened.

The programme of the meeting gives evidence of faithful and commendable work on the part of the Secretary, Dr. K. P. Moore, of Macon. The following law governs the reading of papers:

"No paper shall be read before this Association, by title or otherwise, until a complete copy of such paper shall have been placed in the hands of the Secretary for publication in the Transactions."

The Association will meet daily at 9 A. M., adjourn at 1 P. M. o'clock. Assemble at 3.30 P. M., adjourn at 7 P. M. Further information may be obtained from the Secretary, Dr. K. P. Moore, Macon, Georgia.

Medical Society of the State of Pennsylvania.

The Committee of Arrangements of the Pennsylvania State Medical Society has issued a circular stating that the title of all papers to be read at the next meeting at Pittsburgh, June 10–13, must be sent to the Chairman, Dr. E. A. Wood, not later than May 1. Any inquiries in regard to the meeting will be answered by the Secretary, Dr. W. S. Foster. The address of Dr. Wood is Pittsburgh, Pa.

State Medical Society of Arkansas.

The fifteenth annual meeting of the Arkansas State Medical Society will be held at Little Rock, Ark., May 14–16, 1890.

The hearty co-operation of every member of the Society is earnestly solicited in the effort to secure a large attendance at this meeting and to make it in every way a successful one, and a cordial invitation is extended to all properly qualified physicians not now members of the Society, to become so. For the information of such persons the conditions of membership are given in a preliminary circular, which may be obtained from the Secretary, Dr. L. P. Gibson, Little Rock, Ark.

Secretaries of local Societies are requested to send to the Secretary of this Society, as soon as appointed, a list of the delegates and others who will attend from their respective counties. A final circular, giving detailed information concerning railway rates, hotels and titles of papers promised, will be sent to each member as soon as the necessary data can be obtained.

At the last meeting of the Society the Committee on Arrangements was instructed to prohibit, in the future, the exhibition of secret or proprietary articles in connection with the meetings of the Society.

NEWS.

—Dr. Constantine Goodell has been elected Instructor in Clinical Gynecology in the University of Pennsylvania.

—Dr. Henry W. Stellwagon has been appointed Lecturer on Dermatology in the Jefferson Medical College.

—Dr. Hobart A. Hare has been elected Clinical Professor of Diseases of Children in the University of Pennsylvania, in the place of Dr. Louis Starr, resigned.

—Dr. Alice B. Stockton, of Chicago, was recently the guest of the Russian novelist, Count Tolstoi, and his family.

—Dr. Edwin Arius Kilbourne, Superintendent of the Illinois Northern Hospital for the Insane, at Elgin, died February 27, 1890, at the age of 53 years.

—Dr. Edward P. Stamm, formerly of Philadelphia, died suddenly at Grand Rapids, Michigan, on March 30. Dr. Stamm was graduated from the University of Pennsylvania in 1881.

—Kansas City Medical College held its annual commencement March 10, and conferred diplomas upon a class of sixteen.

—The University of Nashville, Medical Department, held its annual commencement February 26, and graduated a class of 138 students.

—The Jefferson Medical College, Philadelphia, held its sixty-fifth annual commencement April 2. Degrees were conferred on 220 graduates.

—At the forty-second annual commencement of Hahnemann Medical College, of Philadelphia, held April 2, degrees were conferred on 64 graduates.

—Several cases of prolonged sleep and drowsiness have been reported in Cassel, Germany, and in various localities in the province of Hesse. At Schluchten a woman slept for three days. Several similar cases are reported at Neustadt.

—An epidemic of trachoma has attacked a whole regiment of Pioneers at Presburg, Austria-Hungary. Out of 570 soldiers, only 40 escaped. Many became entirely blind, and the regiment was disbanded in consequence.

—The South Carolina Board of Medical Examiners held an examination of applicants for license to practice medicine in that State, on March 5. Of the eighteen who applied for license twelve were successful, four were rejected, and two will be re-examined at the next meeting in April.

—A Chinese laundryman was removed from the Philadelphia Hospital to the Municipal Hospital, March 29, supposed to be suffering with leprosy. The man was admitted to the Philadelphia Hospital some weeks ago, apparently suffering from erysipelas. The disease was, however, diagnosticated as leprosy by the physician in charge, and the patient was transferred to the Municipal Hospital.

—There is a movement on foot at Yale University to secure the erection of a building to be called The Yale Home, where sick students may receive the care and attention which cannot be given in their rooms.

—In Melbourne, Australia, recently a mother and a brother swore to the identity of a corpse found in a creek, as their own daughter and sister, and followed it to the grave; but the missing girl has since been found alive. This is a new illustration of the difficulty of identifying dead bodies even by near relatives.

—A committee has just been organized in Paris under the presidency of Professor A. Fournier, with the view of raising a monument to the memory of the late Dr. Philippe Ricord.

—The influenza has reached Persia, and most of the inhabitants of Teheran, including many of the Shah's household, are suffering from it.

—A man calling himself Dr. Walter E. Reid, and President of the Michigan Spiritual Association, was convicted of using the mails for fraudulent purposes, in the United States Court at Grand Rapids, Mich., April 5, 1890. His sentence was deferred to give his counsel time to prepare a motion for a new trial, the respondent being required to give bail for $1,500.

—It was reported, April 5, 1890, that Dr. L. Z. Lyon, a veterinary surgeon in Baltimore, 72 years of age, had disappeared, and fears were expressed that he had been foully dealt with as he had considerable money in his possession.

—Dr. Theodore S. Wilcox, a graduate of the Eclectic Medical College of New York City, 1875, and Manager of the Sanitarian Hospital and Dispensary in Brooklyn, was convicted on March 27, of obtaining from that city by fraud, the sum of $1,726.55. Dr. Wilcox obtained the money on the strength of the report which he presented to the Board of Estimate. It was, however, discovered that the institution was simply a private boarding-house and not a hospital.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

PARIS MEDAL
TO
WILLIAM R. WARNER & CO.

W. R. WARNER & CO. have received a Silver Medal at the Paris World's Fair, being the highest of its kind, in recognition of the following claims:
First.—W. R. Warner & Co.'s Pills, quick solubility and accuracy.
Second.—Reliability and permanency unsurpassed.
Also for Warner & Co.'s Effervescent Salts.
First—Superior effervescing properties.
Second.—General elegance, excellence, and stability.

PHYSICIANS SHOULD BE CAREFUL TO SPECIFY WARNER & CO.

☞The coating of the following pill will dissolve in 4½ minutes.☜

PIL: CHALYBEATE COMP.

(WARNER & CO.)

Nux Vomica is added as an ingredient to Pill Chalybeate to increase the tonic effect when desired.
Composition of each Pill.—℞ (Chalybeate Mass.), Carb. Protoxide of Iron, gr. 2½. Ext. Nuc. Vom. gr. 1-6.

DOSE—1 to 3 Pills.

Most advantageously employed in the treatment of Anæmia, Chlorosis, Phthisis, Scrofula, Loss of Appetite, etc.

PIL: ANTISEPTIC.

Each Pill contains: Sulphite Soda, 1 gr. Salicylic Acid, 1 gr. Ext. Nuc. Vomica, ¼ gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic is prescribed with great advantage in cases of Dyspepsia attended with acid stomach and enfeebled digestion following excessive indulgence in eating or drinking. It is used with advantage in Rheumatism.

Prepared by WM. R. WARNER & CO.

PIL: ANTISEPTIC COMP.

(WARNER & CO.)

Each pill contains: Sulphite Soda, 1 gr. Salicylic Acid, 1 gr. Ext. Nuc. Vomica, ⅛ gr. Powd. Capsicum, 1-10 gr. Conc't Pepsin, 1 gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic Comp. are prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food.
Supplied upon physician's prescription by all leading druggists. Take no substitute.

Clinical Lecture.

NON-PARASITIC SYCOSIS.

BY HENRY J. REYNOLDS, M. D.,

CHICAGO, ILL.

PROFESSOR OF DERMATOLOGY IN THE COLLEGE OF PHYSICIANS AND SURGEONS; CHIEF DERMATOLOGIST TO THE WEST-SIDE FREE DISPENSARY; GENITO-URINARY SURGEON TO THE WEST-SIDE FREE DISPENSARY, CHICAGO, ETC.

Gentlemen: Almost invariably when a case comes before us for examination we see something in that particular case (the general expression or physiognomy of the disease, or some important points in connection with it) which suggests at least approximately the true condition or disease present. For instance, when we have an eruption that is universally distributed over the body, we at once suspect the presence of some one of the diseases which are characterized in that way; we suspect, for instance, a syphilitic eruption, or the eruption of psoriasis. When we find an eruption characterized by ulceration or destruction of tissue, we suspect the presence of one of the destructive diseases, such as lupus, syphilis, epithelioma, etc.; and when we meet with an eruption confined exclusively to the face, naturally we suspect at once the presence of a disease which is confined principally, if not entirely, to the face; as, for instance, acne, and the two forms of sycosis.

We have here a patient with an eruption not only confined to the face, but also confined to the bearded portion of the face, which narrows the range of diagnosis to that region. Now, as the diseases which affect essentially only the bearded portion of the face are simply two in number, parasitic sycosis and non-parasitic sycosis, we would naturally presume that in the case before us the disease was one of those two. Per-

haps almost everybody has heard of the disease commonly known as barber's itch, technically termed tinea sycosis, parasitic sycosis, tinea barbæ, or tinea of the beard. It is one of those diseases confined to the bearded portion of the face, and owing to the popularity of the name, or the supposed frequency of the disease, many cases of eruption in this locality are at times, even by physicians, loosely designated by that name, as has been done in this case. The disease to which I shall confine my remarks to-day, and which this case represents, though occurring in the same locality, being somewhat similar in its behavior, and bearing a similar name, it must be remembered is an entirely separate and distinct affection. It is known as simply *sycosis*, or in contradistinction to the parasitic disease already referred to, *non-parasitic* sycosis. The case before us then is one of *sycosis*, or *non-parasitic sycosis*.

In order to study more intelligently the various manifestations seen in this case, it is advisable, first, that you get some idea of the general characteristics of the disease.

As to *general appearance* in an ordinary well-marked case of sycosis we generally find an eruption which is distributed equally on both sides of the bearded portion of the face, characterized in a general way by some diffuse redness, usually some crusting, some papules and pustules, more or less thinning of the hair at times, and occasionally some larger lesions almost approximating small tubercles in character. We may at the same time find some lesions on other portions of the body, that is, on the hairy portions, such as the scalp, upper lip, eyebrows, the axillæ or pubes. Any of these hairy portions of the body may be affected by sycosis; but as I have already intimated, it is usually confined to both cheeks.

The disease is almost invariably met with in males, and is necessarily, as regards the face, confined to the bearded portion. It occurs after the age of puberty. It begins as one or several reddish papules, and penetrating each papule we find a hair—in other words, the papule is located around the hair, the inflammation producing it being confined to the hair follicle and the peri-follicular tissues. In addition to these papules, we always have some diffuse redness, this redness extending from one papule to the other. To express it more clearly, we have no healthy skin between the papules. Inasmuch as we have an inflammation of the hair follicles and the peri-follicular tissues, with evidences of diffuse inflammation extending from one papule to the other, we must, as a natural consequence, have more or less infiltration of the tissues and a certain amount of thickening of the flesh. Occasionally several of these papules are situated so close to each other that they seem to run together in one mass and form a slight elevation resembling a tubercle. Not only are these papules and the redness found on one cheek or one side of the face, but, as a rule, to which there is perhaps no exception, we find the same condition on the opposite side of the face. It is, in other words, a symmetrical disease, being distributed on both sides of the face in a similar manner. When we find the eruption confined to the upper lip it also bears that symmetrical character.

Now, as these papules are inflamed, sooner or later, we have the formation of pus and they become converted or transformed into pustules, each pustule, as in the case of the papule, being penetrated by a hair. These are very important points for you to remember, simple as they may seem; because they are to a certain extent pathognomonic symptoms of sycosis. Still further, in addition to the presence of pustules, especially if the hair be long, the pus is retained on the surface, where it dries down into scabs or crusts. This particular characteristic is conspicuous if the hair of the locality is allowed to grow long, or if the part is untreated. It is a disease characterized in its well-marked state by a mass of crusting, very much greater than we see in this case.

Now, as regards the hairs in the part affected. I have already stated that the disease is confined essentially to the hair follicles, and as a consequence the hair must be involved in the diseased process. We find, as I have already intimated, that many of these hairs are surrounded by papules. When these papules advance to the stage of pustules, the hair bulb or hair root is involved; and wherever the pustules form we have more or less breaking down of tissue. The hair becomes loosened in the follicles in time, and on examining we find that those which are situated in the pustules may be very easily extracted. This particular characteristic of loose hairs, however, is only found in the hairs that are situated in the pustules. The remainder of the hairs are always found firm in the follicles, differing in this respect in a striking manner from

some other diseases, such as parasitic sycosis, for instance. The remainder of the hairs are always firm and they are never brittle or broken off. There is very rarely any constitutional disturbance of any consequence in non-parasitic sycosis, although we frequently find these patients more or less anemic and lacking in general vitality. As regards subjective sensation, there is very little itching, but the sensation is that of burning, pricking or smarting. On account of this destructive character of the disease, —to which, however, the word destructive should scarcely be applied,—we have the formation of scars; the follicle becoming obliterated leaves naturally a depression or scar. As a natural consequence, when the follicles are destroyed the hairs are not reproduced, and we have a certain amount of thinning or baldness of the part remaining, which is an important characteristic, and one which is not met with until the disease has existed for some length of time. It is an extremely chronic affection.

Now that you comprehend fully what constitutes a case of sycosis, let me direct your attention to a consideration of this particular case.

This man is fifty-two years of age, a native of New York, a sailor by occupation. He has had the eruption a little over a year. He says it broke out while he was cruising on the Gulf of Mexico, shortly after he had been shaved in a New Orleans barber shop. On arriving at Vera Cruz a doctor told him it was the barber's itch. He was treated in New Orleans for barber's itch, and has been treated by several physicians since that time, the diagnosis being barber's itch, psoriasis, eczema, etc. The majority of these physicians, however, he says, diagnosticated it as barber's itch. He has been more or less unfortunate with the affection and is very anxious to get rid of it. He has for our benefit artistically arranged a list of the various treatments he has had, the remedies being first classed under the general head of *applications*, and then under the sub-headings of *washes*, *salves* and *soaps*. With your permission, I will read this list as he has it arranged. It will at least tend to show the chronic character of the disease, and at the same time show to some extent the opinions and views of the various medical men whom he has consulted. Under the head of *washes*, we have cocaine, chlorodyne, sulphurous acid 1 to 20, carbolic acid 1 to 20, 15 and 10, alcohol and washing soda, alcohol, pulverized alum, borax and sweet oil, one ounce each, add four ounces rain water—shake. *Salves.*—Blue ointment, ox. mercury (yellow), ox. zinc (plain) and combined with iodoform, tar, sulphur, etc., iodine salve, cereate of opium, sulphate of copper and zinc ointment, oleate of copper in lanolin, carbolated vaseline, cuticura salve and soap, flax seed poultices. *Soaps.* Sublimate soap, pine tar soap, castile soap.

As he passes around among you, I would like to have you examine carefully the characteristics I have referred to. You notice first the general appearance of the disease, it being equally distributed on each side of the face. You find, as you examine closely, the characteristic papules penetrated by hairs. You find the pustules also penetrated by hairs. You notice also the diffuse redness. You observe a thinning of the hairs also, although that is not very easily discerned in this case. Notice the tendency to the formation of crusts. You have already learned of the chronic character of the disease in this case from the numerous remedies he has used. You will notice that the hairs are all firm, except those surrounded by a pustule. You notice in several places a slight scar, which is not well marked on account of the disease not having existed a great while.

Etiology.—Now, as to the etiology or cause of the disease. As the disease is confined primarily to the hair follicles, it would seem that the hair were in some way implicated. There are a number of other elements that may be enumerated as probable etiological factors, such as the irritation of shaving, especially with a dull razor; a strumous diathesis, etc. We frequently see in a healthy individual after shaving, irritation of the hair follicles, and occasionally some reddish points or small papules formed upon the bearded portion of the face around each hair. A dull razor necessarily pulls on the hairs more or less, and in that way irritates or acts in a traumatic way upon the follicles. If there is any eczematous or natural constitutional tendency to disease of the skin, a little irritation of this kind would irritate and aggravate the disease, if it might not really produce it in some cases. The disease being frequently met with at about the age of puberty, it would seem probable that the natural physiological activity of the parts incident to the development of the hairs at that age must have some tendency to produce it,

as a physiological activity is very easily perverted into a pathological one.

As regards constitutional causes, while the disease may be said to be principally local in character, it is entirely probable that, if it is not actually produced by constitutional causes, it must certainly be aggravated or prolonged by certain constitutional conditions, as most every local disease is more or less influenced by the constitutional condition of the patient. Further than this there is nothing definitely known in regard to the etiology of sycosis.

We must not let this opportunity pass without a few words in regard to the assertion by the patient that he contracted the disease from the barber's shop. Almost invariably a patient with sycosis associates his disease with the barber shop, though the disease is non-parasitic sycosis and not barber's itch. The reasons are these: In the first place, though the disease is non-parasitic and not contagious, it is probable that one of the principal exciting causes may be justly traced to the barber shop or to the irritation of the last shaving act, the pulling of a dull razor naturally having an exciting effect. In the second place, nearly all men are familiar with barber's itch as a disease affecting the face and as one sometimes propagated through the medium of the barber shop, and they therefore naturally regard it as barber's itch (parasitic sycosis) and unjustly censure their barber.

Pathology.—As to the pathology, the parts essentially concerned are the hair follicles and the peri-follicular tissues, which are inflamed. As I have before remarked, we have some general inflammation of the tissues between these papules and some deposit of exudate in the tissues.

Diagnosis.—The diseases most likely to be confounded with non-parasitic sycosis are parasitic sycosis, eczema, acne, and possibly syphilis. By careful attention to the diagnostic tables which I now give you there need be no difficulty in any case.

SYNCOSIS.	TINEA SYCOSIS.
1. No reliable history of contagion.	1. Reliable history of contagion at times.
2. Starts as discrete papules.	2. Starts as ordinary ringworm patch.
3. Diffuse general redness.	3. No diffuse redness.
4. Characterized by papules and pustules, each of which is penetrated by a hair.	4. No papules nor pustules, but deep lumps.
5. Symmetrical.	5. Not symmetrical.
6. Hairs always healthy, and none loose except those surrounded by a pustule.	6. Hairs dry, brittle, broken off, and most of them loose in the diseased patch.
7. Microscope does not reveal any parasite.	7. Parasite readily discovered with the microscope.
8. Not liable to be accompanied by ringworm of the non-hairy parts.	8. Liable to be accompanied by ringworm on the non-hairy parts.

SYNCOSIS.	ECZEMA.
1. Little itching.	1. Intense itching.
2. Never vesicles nor serous exudation.	2. Generally vesicles and serous exudation at times.
3. Confined to bearded portion of face.	3. Rarely confined to bearded region.
4. Symmetrical.	4. Not symmetrical.
5. Papules and pustules penetrated each by a hair.	5. Papules and pustules not penetrated by hairs.
6. Generally occurs after puberty.	6. May occur at any age.
7. Generally met with in males.	7. Met with in females as well as in males.
8. Always a tendency to chronicity.	8. Rarely tends to chronicity.

SYCOSIS.	ACNE.
1. Confined to bearded portion of face.	1. Never confined to bearded portion, but affects entire face.
2. No comedones present.	2. Always find comedones intermingled with the eruption.
3. Diffuse redness.	3. No diffuse redness.
4. Papules and pustules are penetrated by hairs.	4. The papules and pustules are never penetrated by hairs.
5. Sycosis never found on the face of females.	5. Common in females.
6. Never met with until adult life and after the development of the beard.	6. Generally first met with at puberty and before the development of the beard.
7. Accompanied by pricking, smarting or burning sensations.	7. No subjective symptoms.
8. Tends to chronicity.	8. Tends to disappear spontaneously in adult life.

SYCOSIS.	SYPHILIS.
1. No history of syphilis.	1. Generally have reliable history of syphilis.
2. Eruption usually confined to the bearded region.	2. Very rarely confined to the bearded region.
3. Never affects the non-hairy skin.	3. Affects the non-hairy skin and the hairy parts alike.
4. The papules and pustules penetrated by hairs.	4. The papules and pustules never penetrated by hairs.
5. Always a diffuse redness.	5. Rarely any diffuse redness.

6. Always symmetrical.	6. If confined to the bearded portion of the face, never symmetrical.
7. Chronic, but never ulcerates.	7. If chronic, always proceeds to ulceration.
8. Accompanied by pricking, smarting or burning sensation.	8. Little subjective sensation.
9. Secretions not necessarily accompanied by an offensive odor.	9. Generally accompanied by a very offensive odor.
10. Will not yield to syphilitic treatment.	10. Generally yields readily to syphilitic treatment.

Treatment.—The disease being a local one and caused, or at least aggravated or perpetuated, by the irritation of the hairs in the follicles, the treatment must be more or less local in character, and the hairs must receive due consideration. Although this disease is not necessarily caused by constitutional derangement, inasmuch as every local disease is influenced more or less by the constitutional condition, and sycosis is sometimes partly caused by the constitutional condition, the treatment must be directed to that condition also. Like most other diseases the local treatment must vary more or less with the conditions present, it must be stimulating or soothing according as the part is actively inflamed or in a subacute or chronic state of inflammation.

Now, very frequently the cases as we meet with them have a great mass of crusting on the surface; then the treatment must be directed first to the crusting. If the beard is long, it is generally well to clip it as closely as possible before beginning treatment; then the crusts must be softened up by the application of some oleaginous preparation. If the inflammation is acute, a linseed poultice is better than the oleaginous preparation; because, in addition to softening the crusts, it will allay the acute inflammation. When the crusts are thoroughly softened, they must be carefully and gently removed with soap and warm water. If the inflammation is very acute it is well to again apply some soothing application, such as some mild ointment or carron oil (equal parts of oil and lime-water), lead and opium wash, etc. As soon as the acute inflammation has passed off, the hairs that act as foreign bodies to the hair follicles must be either removed by epilation or extraction or carefully shaved off. The better way, probably, is to extract the loose hairs from the pustules. Shaving, however, sometimes answers the purpose, inasmuch as the hairs, when cut close to the surface, do not irritate the inflamed follicles by their movements as much as when they project to any extent. After the loose hairs are picked out or the parts are shaved, or both, as the case may be, apply remedies as you would to any diseased surface with a view to healing it up. In this case we will first apply citrine ointment —one drachm to eight of lard or vaseline— three times a day. Very soon the crusts will be softened; and then we will instruct the patient to wash off the crusts with soap and water. After that, we will have him dust on an impalpable powder of boric acid. This is about all the treatment we can give him at present. We will then watch him, and from time to time, as the symptoms seem to indicate it, after the crusts are removed, we will either shave the hairs off close with a sharp razor or extract them. Sometimes a plaster of diachylon ointment, applied on linen and allowed to remain, is very effective, as it seals up the part from atmospheric and other irritating influences, and at the same time stays the parts so that the hairs do not, by their movements, irritate the follicles.

COMMUNICATIONS.

A CASE OF ABORTION WITH SEQUELLÆ.

BY A. C. HAWLEY, M. D.,

EATON, OHIO.

About the first of April, 1889, I was consulted by Mrs. Y., whom I had delivered of a baby nine months before, as to the probability of her being pregnant. Some symptoms were present which had suggested pregnancy to her. Most prominent among these had been the absence of her menstrual flow at her last regular period, yet, as she was nursing so young a child she could scarcely think that she was pregnant and dreaded the idea under any circumstances. I told her that the probability was that she was so. She hinted at interfering with the progress of gestation; but this I discouraged from a moral point of view, showing her the great risk she would run of sacrificing her life, and if not her life, her health.

Here the case rested until the first of May, 1889, when the patient's husband came into

my office, stating that his wife was not feeling very well, and that she had been having a slight "wasting" for a few days, though he thought it was not serious. I elicited enough from him to conclude that the probabilities were that an abortion was threatening and that the hemorrhage was serious, and I had better see her at once. The place was seven miles distant in the country; and, when I arrived at the bedside, I found that the hemorrhage had been profuse, although not yet enough to produce any immediate alarming effects upon the patient. Upon inquiry I found that two weeks before this hemorrhage the patient was holding a mare by the bit, and the animal, in trying to free itself, had given the woman a severe jerk which lifted her off the ground. This immediately caused a free hemorrhage which lasted for a short time. Since then there had been no appearance of bleeding until the present hemorrhage, which started when she made an attempt to lift the baby from the floor. She knew nothing of what had passed from her during either of her hemorrhages. She had seen nothing but the blood; and, consequently, it was one of those obscure cases which we all dread so much to meet. Upon digital examination I found the os but slightly dilated. There had not been any pain. Believing that the process of gestation was too far interrupted to prevent abortion, I set about to produce pains and to effect expulsion of the contents of the uterus, well remembering the oft-repeated maxim of Professor W. H. Taylor that "an empty uterus is the only safe uterus."

I thoroughly tamponed the vagina with cotton balls, and left the patient, to be seen again early the following morning.. When I returned I found there had been no pains and the hemorrhage had been so slight as to hardly color the cotton next to the os. I now concluded that the contents of the uterus had been thrown off the day before. Here I instituted a cross-examination and found, from the husband, that he had seen the day before what he had supposed was a fetus, but whether or not any of the membranes had passed, he did not know. For the sake of safety I tamponed again, and returned in the evening to find no pain and a slight discharge, as in the morning. But yet, to be doubly certain and, if at all possible, to elicit pains and the expulsion of the contents of the uterus without introducing instruments, I introduced a sponge tent and then tamponed the vagina, and ordered perfect quiet and teaspoonful doses of the fluid extract ergot every three hours. I returned in the morning to find that no pains had been produced, but, on removal of the tent I found a good sized shred of membrane had been brought away.

I now thought the trouble ended; but, for the satisfaction of the family and my own comfort, I had my father, Dr. Albert Hawley, called. After a careful examination we agreed that, in all probability, the danger from hemorrhage had passed, and thought that with tonics and constitutional treatment, the patient would get along and soon be able to be around.

I visited her on the fourth, fifth and sixth of the month. At the last visit I found that she was doing so well that I dismissed the case, congratulating myself that I had disposed of one of those dreaded obscure abortion cases in a satisfactory manner. On the morning of the eighth of May a man drove up to my office, with his horse all in a foam, and asked me to come as quickly as possible to Mrs. Y., saying that she was almost dead. I hurried to the scene, and found my patient bleeding frightfully. The bed was saturated, the patient was pulseless, almost voiceless, and fainting repeatedly. I immediately dispatched the husband for my father, while I proceeded to inject cold water (there being no hot water in the house) into the vaginal canal, and gave a hypodermic injection of an aqueous solution of ergotine, which I always carry in my obstetrical bag. These means not being as effectual as one would wish in such emergencies, I thrust my hand into the vagina and my finger through the cervical canal, hoping thus to stop the hemorrhage mechanically, and at the same time to remove the offending contents of the uterus, which I found to be the mass of the membranes of a pregnancy of about eight or ten weeks' duration. These membranes were firm and adherent to the walls of the uterus. I tried to loosen them with my finger and a dull curette, and to drag them away with the uterine dressing forceps, but failed. All this time the patient was fainting repeatedly and death seemed imminent. After the arrival of my father, we again attempted the removal of the membranes, but it was only after repeated attempts and failures that I was able to bring away a mass of "fleshy degenerated" membrane, and by one or two more like manipulations separated and brought away all the membranes, and the

operation was at last completed. The woman was almost lifeless. We administered stimulants freely, and I remained by her bedside all night; and, to my delight, found that she gained rapidly, and that by morning the heart's action was good. I left her early in the morning, ordering perfect quiet, whiskey, quinine, and tincture of chloride of iron eighteen to twenty drops four times a day. From this time on there was no hemorrhage, and the patient improved unusually rapidly, until the morning of May 20, when I found her complaining of severe pain in the right side. There was no acceleration of the pulse, no elevation of temperature, no cough, and but a slight increase of rapidity of respiration. With hot moist applications and light anodyne treatment the pain was soon allayed, and the patient rested well until May 22, when the pain again appeared and became fairly seated about the region of the fourth and fifth ribs, and all the symptoms of a well marked severe case of pleurisy were present excepting the fever—the temperature not being more than one degree above normal. Effusion, which covered a little less than two-thirds of the lung, took place.

This trouble was subsiding nicely when, in a few days, a lobar pneumonia of the right lung developed (the same lung which was being drowned by the pleuritic effusion), which, with the effusion, almost excluded the air from this lung. The prognosis in the case grew grave, but within a week or ten days the symptoms began to ameliorate, and the indications were that she would soon recover. But no sooner had the right lung begun to act fairly well, than the left was also attacked with pneumonia, and the symptoms grew graver than they yet had been. The patient became discouraged; her appetite and strength failed; and the host of attendants of long-continued sickness were present. But, after some time, the disease began to abate, and our patient was again on the high-road to recovery, and rapid strides were made.

She had so far recovered that she had begun to want to get up to stool, when, on the evening of June 7, she made her first attempt to get out of bed. Soon after returning to bed she began to complain of pain in the calf of the left leg; and, on my return in the morning, I found her suffering greatly from the pain. There was no tenderness except in the calf, and no pain along the course of the larger veins; but on the following day I found the entire limb swollen, and the region of the larger veins very painful and the veins cordy. The temperature was 102° F. The limb was well elevated, and heat was kept applied constantly, and an occasional anodyne application was made, and morphia was given to relieve the pain. This treatment was continued for several days before any change towards improvement was noticeable. Perfect quiet was observed for six or eight days, lest the slightest disturbance might liberate the thrombus, which I believed to be the cause of the phlegmasia-dolens. By the eighth or tenth day the heat and pain had diminished, but it scarcely need be remarked that the swelling had not then subsided; nor has it yet. I dismissed the patient about June 20, on the high-road to recovery. She gained rapidly, and by July 4 was going about on crutches. By the twentieth of the month she had dispensed with these, and at present she is able to do all her work as a farmer's wife. Her limb is gradually growing smaller and her general health was never better.

TROPHO-NEUROSIS AS A FACTOR IN THE PHENOMENA OF SYPHILIS.[1]

BY G. FRANK LYDSTON, M. D.,

CHICAGO, ILL.

In studying some of the late, or sequelar, lesions of syphilis, particularly those involving changes in the bony structures of the head and face, I have been forcibly impressed by certain characters of the lesions which seem to depend upon a more occult series of pathological changes than those to which they are usually accredited. Some of these characteristics pertain also to many of the lesions of the active or secondary period of syphilis.

The relation of certain syphilitic phenomena to organic or functional disturbances of the nervous system—and particularly the sympathetic system—is certainly manifested here and there along the whole line of morbid phenomena developed in the course of the disease. The so-called syphilitic fever, while an inconstant phenomenon, is present in a sufficient number of cases of the disease to practically settle the question of the

[1] Read at the meeting of the Southern Surgical and Gynecological Association.

relation of cause and effect. The symptoms which we designate collectively as syphilitic fever are, in common with some other febrile constitutional disturbances, undoubtedly dependent upon the action of a special poison upon the sympathetic nervous system. It is logical to infer from what we know of the physiology of the sympathetic system, and particularly of those functions of the sympathetic, which we term trophic, that the majority of fevers—if not all—are directly dependent upon the action of the specific poison upon the sympathetic ganglia, which action is manifested by the disturbed metabolism and the resulting phenomena of fever. So in the case of syphilis the poison may produce so profound an impression upon the sympathetic ganglia that the trophic function of this portion of the nervous system is disturbed, with an attendant perversion of tissue metabolism, a resultant excessive production of animal heat, and the accumulation in the system of the toxic products of perverted physio-chemical change. The fact that so-called syphilitic fever is not a constant phenomenon, but affects only a certain portion of individuals attacked by syphilis is explicable upon the ground of idiosyncrasy.

The argument that syphilitic fever is the result of an impression produced by the syphilitic poison upon the sympathetic nervous system does not necessarily imply—nor do I intend it to do so—that the syphilitic fever is a part of the natural course of the disease. On the contrary, I believe that it is accidental and the result of idiosyncrasy. We know that different individuals are variously affected by the constitutional impression of organic poisons. Certain individuals are affected by urticaria or erythema upon the ingestion of shell-fish, this result being especially apt to follow when the particular article of food is not perfectly fresh or was not in an absolutely healthy condition when taken for food. Some persons are seriously affected by the ingestion of certain vegetables—especially if partial decomposition has occurred. Canned vegetables, and especially tomatoes, are liable to impeachment upon this ground. If it is fair to infer that by virtue of idiosyncrasy the nervous system of certain individuals may be morbidly impressed by certain food substances which are innocuous to the majority of individuals, it is certainly fair to assume that in the case of so powerful an organic poison as that of syphilis, with which a large number of individuals are inevitably inoculated, certain special and exceptional phenomena might be produced in some persons.

Attendant upon, or following the syphilitic fever, or occurring independently of it, we have a characteristic manifestation of syphilis, which in cases unmodified by treatment is probably always present in greater or less degree. I refer to syphilitic roseola. This eruption has been shown to be unlike the other phenomena of syphilis in that it is dependent, not upon a localized collection of proliferating syphilized cells, but upon vaso-motor disturbances, the essential objective element of which consists in dilatation of the capillaries in localized areas of the skin. This, as far as we are able positively to determine, is dependent upon the impression of the syphilitic poison—virus, bacillus, degraded cell, or whatever term may be selected to designate it—upon the central sympathetic system. This impression is essentially the same as that produced by certain vegetable poisons. It is not, however, dependent upon idiosyncrasy, although it may be modified by it; thus we find in some individuals a very marked roseola, in which the lesions are disseminated over a large area of the integumentary surface and are very prominent and well-defined; whereas in others we may find upon close inspection perhaps but a single lesion. The gradations between the two extremes are very various. Idiosyncrasy might be advanced quite plausibly as the explanation of this wide variation.

The action of certain drugs given for medicinal purposes is a further illustration of the results of various poisons upon the sympathetic nervous system as manifested by the appearance of morbid cutaneous phenomena. Belladonna, quinine, opium, copaiva, chloral, salicylic acid and numerous other drugs have been found to produce, in exceptional cases, an efflorescence upon the skin. The rarity of such phenomena, in conjunction with other proofs of idiosyncrasy and the known properties of these various drugs as far as their action upon the skin is concerned, are positive evidences of their neurotic character.

The lesions of syphilis which succeed the roseola have been so positively demonstrated to be dependent upon a localized deposit and proliferation of syphilized cell material that it would appear to be impossible to apply the neurotic theory to them. It is only necessary, however, it appears to me, to direct attention to the marked symmetry

which characterizes the peripheral phenomena of syphilis to at once suggest the probability of a central nervous element in the production of the various lesions. It is admitted, to be sure, that a symmetrical development of eruptive lesions occurs in some other affections. It will be found, however, that in them a nervous element is either positively demonstrable, or the skin lesions are so abundant and general that it would be impossible that they should be otherwise than symmetrical.

As a most positive proof of the relation of eruptions of the skin to nervous disturbance of a presumably trophic character, I have but to allude to herpes zoster. In this disease we find an accurate delineation of the course of the affected nerve by the eruption, and a very manifest local disturbance of nutrition of the affected tissues. Generally some portion of only one side of the body is affected by this disease. It is sometimes bilateral, and consequently of a more serious character than usual. Some of the later lesions of syphilis are unilateral; and, as will be shown by a case shortly to be described, almost as plainly referable to the distribution of a particular nerve as is the case with herpes zoster.

Professor Otis, following Biesiadecki and others, has shown that the predilection of syphilitical material for the papillæ of the skin, is due to the fact that it is at this point that the arterial, venous and intervening lymphatic capillaries come into the most intimate contact—in other words, that it is in the papillæ of the skin that the narrowest points in the circulatory and lymphatic flow are to be found. The affinity of the syphilitic process for lymphatic structures explains the rest; and we have at various points in the superfices of the body a localized heaping up of the so-called syphilized cells. We have, however, in the roseola, localized and circumscribed phenomena which are not satisfactorily explicable upon anatomical grounds. Why does not the roseola appear in one continuous blush over the entire surface of the body? Is it not because the impression of the syphilitic poison upon the system is manifested through a vaso-motor disturbance of the function of the sympathetic ganglia at certain terminals in the skin? Dr. Otis accepts the neurotic origin of the roseola, and it is a matter of surprise that he should seek for a local anatomical explanation of the development of, for example, the syphilitic papule. In view of the logical explanation of the roseola, would it it not be fair to infer that a similar condition of affairs prevails in the case of the other eruptions? That is, that, as a consequence of an impression made by the syphilitic poison upon the sympathetic ganglia, their trophic functions are disturbed with a consequent disturbance of nutrition and perverted tissue building at certain points upon the periphery or superfices of the body? I do not know whether this explanation of the secondary eruptions of syphilis has ever been advanced; but it has for some time appeared to me to be the most logical explanation of the phenomena of syphilis. It is particularly satisfactory, from the fact that it covers not only the roseola and papule, but every other lesion which may occur throughout the entire course of syphilis.

There is, perhaps, no morbid phenomenon characteristic of active syphilis which is more difficult of explanation upon purely mechanical grounds than the alopecia which occurs during the secondary period. Very few cases, if any, which are unmodified by treatment, escape this disagreeable symptom of the disease. Indeed, under the most careful and scientific treatment, a greater or less degree of alopecia is frequently observed. The shedding of the hair is limited chiefly to the scalp. The eyebrows are affected, but the beard is little, if at all, involved, as a rule. Other hairy parts of the body are not generally involved, even though there may be a quite general eruption over the surface of the body. Should destructive lesions occur in any situation supplied by hair, a temporary or even permanent shedding will be likely to result. The manner in which the hair is shed from the scalp is most striking and characteristic, in most cases. Instead of there being a general shedding, the process seems to affect the scalp in spots, as a consequence of which the head assumes an embarrassing piebald appearance, which he who runs may read. Otis and others attribute this alopecia to an accumulation of syphilized germinal material in and about the hair follicles, this deposit producing mechanical impairment of nutrition of the hair, as a consequence of which it is cast off. Strange to say, however, if this theory be correct, lesions of the scalp of sufficient prominence to attract attention are quite rarely associated with alopecia. A few small papules, pustules and crusts are occasionally found, but hardly ever in sufficient amount to account for the extensive falling of the hair.

It will be found, to be sure, that at the site of such lesions the hair invariably falls out. Now, it seems to me that, if the syphilitic material had such an affinity for the scalp as would be indicated by the theory of localized cell deposit, the cutaneous lesions of this portion of the integumentary surface would be especially pronounced. It is hardly probable that, in the presence of such an affinity for the hair follicles, a deposit of syphilitic material would accumulate to such an extent as would be sufficient to deprive the hair follicle of nutrition, and yet fall short of a sufficient amount to be perceptible externally. There may be, it is true, more or less accumulation of germinal material in the hair follicles, but there yet remains the necessity for an explanation of its deposition in this location.

From these considerations, I have been led to believe that the alopecia of syphilis is precisely similar to that which occurs in other diseases as a consequence of local malnutrition incidental to disturbed nervous supply and general malnutrition. In certain fevers for example, shedding of the hair is quite common during convalescence—perhaps well along in the period of convalescence. This is due to a general perversion of nutrition which must necessarily affect an epidermal structure of a low grade of vitality, such as the hair. This perversion of nutrition is in my opinion due to a greater or less extent to disturbance of the functions of the sympathetic nervous system—in other words, to a tropho-neurosis. Various morbid disturbances of the nervous system are known to affect the vitality of the hair. Thus, fright has been known to induce a blanching of the hair, unquestionably dependent upon perversion of the functions of the sympathetic ganglia. Neuralgic affections of the head are well known to produce both blanching and falling of the hair, perhaps limited to the distribution of the terminal filaments of a single nerve. As a further illustration of the relation of malnutrition, probably dependent upon perversion of the functions of the sympathetic nervous system, to falling of the hair, may be mentioned the alopecia resulting from the excessive use of arsenic internally.

The relative immunity which the beard of the male enjoys, as compared with the hair of the scalp, is probably dependent upon the greater intrinsic strength of the hair growth and the higher vascularity of the tissues of the face.

It would appear that syphilitic infection not only has a peculiar affinity for the sympathetic nervous system, but that this affinity is particularly marked in the case of the upper or cervical portion of the sympathetic. The proportion of lesions about the head, face and mouth is relatively much larger even under the best of treatment, than in other portions of the body. The parts supplied by the fifth cranial nerve appear to be especially susceptible. Very many of the cases with which I meet in private practice escape general cutaneous eruptions under appropriate treatment. Few, indeed, no matter how thoroughly they may be treated, are not affected at one time or another with lesions of the lips, inner surface of the cheeks, tongue, throat and scalp. I find that falling of the hair, sore throat and mucous patches are to be anticipated, in the larger proportion of cases, in spite of the most careful treatment. In my experience I have had very few cases in which, with conscientious attention to treatment, the patients have been annoyed by cutaneous eruptions, bone lesions, etc.; but I have had a number in which oral and pharyngeal lesions proved a source of great annoyance. Even in the late and seqular syphilides this same predilection for the structures of the face and throat is manifest. Cases are frequently met with in which the initiatory and active periods of the disease have been passed through without serious trouble, when serious destruction of the nasal, palatal and maxillary bones has developed suddenly and without warning. Many cases of serious destructive ulceration of the pharynx are met with, as remote manifestations of syphilis, in cases in which annoyance has been escaped during the earlier periods of the disease.

The affinity of the syphilitic process for the iris may possibly be explicable from the important function of those filaments of the sympathetic system supplied to this part; in other words, the local accumulation of cells in the iris may be incidental to disturbances of nutrition dependent upon the impression of the syphilitic poison upon the central sympathetic system.

[TO BE CONCLUDED.]

—Jambul, given to animals previously made diabetic by phloridzin, is said to correct the pathological excretion in animals experimented upon.

PNEUMONIA: ITS TREATMENT.

(THIRD PAPER.)

BY HIRAM CORSON, M. D.,
CONSHOHOCKEN, PA.

I do not wish to convey the impression that the means which I shall recommend for the heavy congestions and speedy inflammations which occur—the kind which so generally prove fatal under the reformed (?) treatment—are needful in all the cases included under the name pneumonia by many practitioners. I have in my mind measures to save patients from death who suffer from the most acute and violent attacks. I have read Prof. James Tyson's paper; and though it is, as all his writings are, earnest and full of thought, and though this one is so greatly in advance of the treatment by Prof. Osler, whose place as clinical teacher he now fills, I feel that there are a few opinions in it which he will abandon if he should chance to see the great relief brought to patients suffering from suffocation (such as was borne by young Mr. Blaine), by a judicious blood-letting. Such cases I shall present, and show how immediate the relief. Again Dr. Tyson has said: "I am as much opposed to the *routine bleeding* in pneumonia as I am to the *let alone policy* of to-day," though he never bled a case. To this I answer, that we have no routine treatment, but conscientiously and under the guidance of long and successful practice with various measures, determine when any one, or more of them is needed, and use it unawed by popular clamor. Before reporting the cases so similar to Mr. Blaine's, allow me to say that I believe the popularity of some of the new medicines and opposition to the old depleting treatment of Professor George B. Wood, Professor N. S. Davis, and other eminent authors, grew out of the fact that many physicians called trifling bronchial affections pneumonia, prescribed some favorite arterial sedative, or aromatic spirits of ammonia, so relied on by Dr. Osler, or carbonate of ammonia, and as the patient got well, vaunted the remedy as useful in pneumonia. Then, when a real case like that of Rev. Dr. Vinton, Dr. S. W. Gross, Judge Mercur, Walker Blaine, or the many who have fallen victims to this boasted treatment, is met with, these medicines are tried and the patient is lost.

In the MEDICAL AND SURGICAL REPORTER of November 30, 1889, there is reported a clinical lecture by Professor Da Costa, describing a case which, on carefully reading, I could not regard as one of pneumonia. There was some pain in the side of the chest on *forced* inspiration; no rusty-colored sputum; but strong pains in the leg, below the knee, as the prominent symptom. It appeared to me to be a case of one who, from exposure, was beset by pains in various parts of the body with soreness of the muscles, and with general malaise, all of which might be remedied by an anodyne and a few hours' rest in bed, and the patient be put on his feet again. I hope your readers will read the case carefully and pass judgment on it. Distrusting somewhat my judgment in the case, inasmuch as it came from such a distinguished diagnostician, I wrote to three subscribers to the REPORTER, men of much experience and undoubted truth, for their opinions.

One of them, a man of distinguished ability and a practitioner of many years, wrote as follows: "As to the article to which you refer in the REPORTER, I am not at all convinced that the case was one of pneumonia. From the report of it, which at best is exceedingly indefinite to form any decided conclusions from, I should rather incline to regard it as a case of malarial fever, with congestion of the lungs as the complication which misled the diagnostician. At any rate, so far as drugs did any good, I think quinine was the one to which it could most reasonably be ascribed. I may say, too, that my assistant, who has been interviewed in regard to the case, is of the same opinion that I am."

The other two could not recognize the case as one of pneumonia. But why need I notice it? The patient recovered. Yes, he recovered, as many patients do even when we err in treatment. But I review the case to show that it is the regarding of such cases as pneumonia which leads to the belief that the medicines used in their treatment may be relied on in any case of that disease, and thus inexperienced physicians may be led to rely on them in acute dangerous cases, and the patient be lost. I have great respect for Dr. Da Costa, know how eminent he is as a diagnostician, but that is no bar to my holding an opinion different from his. I do not want the minds of students led away from the suffering lung in real acute pneumonia by diffused pains in other parts of the body—"or pain in the lower part of the right leg and foot"—or

even, in the "region of the ileo-cæcal valve." I have no doubt that this is now down in every note-book that was at the lecture, and hereafter, should one of the audience be called to a patient suffering pains in those places he will diagnosticate "pneumonia—with absence of rusty-colored sputum." If there are no means to cure such cases as those of Dr. S. W. Gross, Dr. Bruen, Judge Mercur, and scores of others with whom the reformed practice failed, then it is time to look about for something better than the present popular but inefficient treatment.

I shall now give the views of some practitioners well acquainted with the properties of the various remedies in favor now, and who have also had many years' experience—actual experience with other measures now so greatly and ignorantly denounced. How strange it seems to those who practiced when blood-letting was freely used in pneumonia and other inflammatory diseases, to hear men and—worse than all—teachers, who never saw it practiced, prate against it. "What do they say of it?" "That it is never necessary; that it is dangerous; that it does not give relief, but weakens the system, so that it cannot bear the depressing effects of the third stage; and that it leads certainly to heart-failure."

My object, now that I have shown that the disease is a congestion of the lungs quickly followed by inflammation, is to prove that the charges against blood-letting in the treatment of pneumonia and other acute inflammations of the body are not well founded, but that venesection is a most safe and efficient remedy, which, when judiciously used, prevents the third stage in pneumonia, and also heart-failure by curing the disease before either condition is reached—conditions which I have prevented many times. Surely there is no man, experienced in the treatment of pneumonia, who does not know that the disease can be arrested before the inflammation has reached the third stage: a stage in which Prof. George B. Wood has said, "It is doubtful whether recovery ever takes place."

The arterial sedative practice allows it to reach that stage when the patient does not die early, and he dies then or is crippled with chronic lung disease for life. Where persons are cured by blood-letting in the first or second stages, as they usually are when it is used, they come out of it with perfect lungs. And now for my proofs that we have means to cure the worst cases.

Dr. Wm. McKenzie, a graduate of the Class of 1871, University of Pennsylvania, doing a large practice, writes:

"*Case 1.*—I was called, January 6, to a German, 56 years old, who has always enjoyed good health, suffering with violent frontal headache, pain in the back and limbs, with tight feelings. With these symptoms I diagnosticated *La Grippe.* I prescribed for him, and by January 10 he was down-stairs. On January 13 I was called, and found him in bed breathing with difficulty. He had pain in left side, his face was flushed, and he said he had a chill the previous evening. His temperature was 103°, his pulse 118, and his left lung was filled with crepitant râles. I then saw that I had to do with what would soon be a severe pneumonia, and that if the inflammation was not speedily controlled it would result in death to my patient. I at once bled him freely. I usually bleed in a sitting posture and allow the blood to flow until fainting is produced, but in this case I allowed the man to lie down, and fully twenty-six ounces were taken before there was a change in the rate or character of the pulse. A large blister was then placed on the side and allowed to remain eight hours, then to be dressed with a poultice. When I called in the afternoon I found him very comfortable, breathing easily, with very little cough and only slight pain in the chest. The after-treatment consisted in an expectorant of muriate of ammonia and sulphate of morphia. He steadily improved, and convalesced in a few days. I have practiced since 1871, and every Spring and Fall have had cases of pneumonia to treat. With but few exceptions I have bled them all, and during all these years have had but three deaths. The above case illustrates my treatment. I make no account of age, but find that the old are just as much benefited by blood-letting as the young."

"*Case 2.*—M. S., 63 years old, feeble and much exhausted from nursing her husband, who was buried the day before I was called to see her. I found her with great difficulty of breathing and unable to speak above a whisper, with great pain in the chest and expectorating rusty-colored sputa. She was poor and had to rely on the neighbors for nursing. I resolved to bleed her, and asked for a basin. 'Oh, doctor!' said several of the women present, 'is she not too weak to be bled?' 'Never mind about her weakness; if I do not bleed her she will surely

die, and I propose to do the best for her.' I propped her up and bled her until she fell over in a faint. The arm was then tied up and she was placed in a horizontal position, and in a few minutes consciousness returned. I gave one-sixteenth grain of sulphate of morphia every three hours; and in a week she was well."

"*Case 3.*—While attending the last patient, R. B., 18 years old, and living in the next house, was taken sick. He was strong and robust. He had had a chill the evening before I was called, followed by high fever, rapid and bounding pulse, pain in the side, and expectoration of rusty sputa. He was freely bled, and in a few days was out again. Simultaneously with the last two cases, an aunt of the last one, living only a short distance away, was taken with pneumonia, and was attended by a physician who 'does not believe in blood-letting in any case.' She was a stout, healthy woman, forty-five years of age; and yet she died after less than a week's sickness. Judging from my success in the other cases, I am confident that, had she been bled judiciously, she would have recovered. I regard the responsibility of the doctor in this case as very great, as I was informed that the relations requested him to bleed her. He declined on the ground 'that no well-posted physician in this advanced age of medical knowledge would bleed a patient.'"

Dr. George N. Highley, a graduate of the University of Pennsylvania, 1881, and doing a large practice in Conshohocken, writes as follows:

"*Case 1.*—Pneumonia.—Mrs. S., about 45 years old, mother of ten children, much broken in health by hard work and frequent child-bearing, was taken with a chill in the night of April 8, 1889, and this was followed by high fever. She had complained of her left side for a day or two, and had a cough. I was called to see her on the morning of April 9. I found her lying partly on her left side, her countenance indicating much suffering, and she made great complaint of pain in the left side of the chest, which was measurably increased by movement and by the frequent hacking cough. Her pulse was 100, her respiration 32, her temp. 103°. Her expectoration was scanty, consisting of frothy mucus. Her skin was dry and her tongue coated. Auscultation revealed feeble respiratory murmur, or total absence thereof over the lower half of the left lung. There was dulness on percussion over the same region. Diagnosis: pneumonia. Treatment: half a grain of morphia and eight drops of tincture of aconite were given at once, and the following prescription was ordered:

℞ Potas. citrat. . . . . ℥i
Suc. limonis . . . . . f℥jss
Liq. morph. sulph.
Syr. ipecac . . . . . āā f℥ss
Aquam ad . . . . . f℥iv
M. Sig. A teaspoonful every two hours.

"The next morning, April 10, her case was alarming. She had had no relief from the treatment.[1] The pain and dyspnœa were very great; her pulse was 120; her temperature 104°; her respirations 45 or 50, and rusty sputa were expectorated. She believed death was near, and her distress was extreme. I now bled her about twenty ounces, and this gave her marked relief. The respirations immediately fell to 25; the pulse to 100. I then ordered one-fourth grain of morphia sulphate and the following:

℞ Ant. et potas. tart. . . . . gr. i
Potas. nitrat. . . . . ℥i
Syr. ipecac. . . . . f℥iii
Syr. pruni Virgin. . . . q. s. ad. ℥ii
M. Sig. Teaspoonful every three hours.

"The chest was covered with a layer of raw cotton on the first day; and no other local application was made during the woman's illness. I saw her twelve hours after the bleeding; she had then had some sleep and had been very easy all day. April 11, at 10 A. M., her pulse was 100; her respirations 22; she complained of soreness in the affected side; but had very little pain. I ordered two grains of quinine every three hours, alternating with the mixture. Her convalescence continued uninterruptedly. She was out of bed on the ninth day, and able to perform light house-work about ten days later. After the third day of her illness she was given milk, beef-tea, mutton-broth and the like. Before that time she had taken no food."

Dr. David R. Beaver, also a graduate of the University of Pennsylvania, of the class of 1864, and who has had a remarkably large practice from that time to the present moment, sends the following case, which occurred during the time of the *grippe* epidemic.

---

[1] Strange, wasn't it? as the treatment was of the "reformed" kind.—H. C.

"I was called to see Mrs. C., mother of several children, and about fifty years old, December 12, 1889, and found her suffering from the effects of a chill after a carriage ride late in the afternoon. I prescribed for her and saw her in the forenoon of the next day, when I found her suffering with severe pain in the left side, or lung. There was great dulness in the lower two-thirds of the chest and great difficulty in breathing. She also had pain in the head, and in fact a general congestion of the whole surface, with rusty-colored sputa; all indicating pneumonia or pleura-pneumonia. The pulse was 120, the respirations were 24, the temperature was 103°. Considering the full or plethoric habit of the patient, I did not hesitate a moment, but bled her twenty-two ounces by actual measurement. This gave her the greatest relief; and she so expressed herself. She went on to make a good recovery, and her immediate family and friends were astonished at the result."

Such are the reports made to me by three Conshohocken physicians, the only medical men whom I asked about their treatment of pneumonia. Before making any general remarks on them I feel that the readers of the REPORTER will desire to know why Dr. Beaver added the last clause to his report, namely, "her immediate family and friends were astonished at the result!" They were astonished because so many eminent persons have been quickly carried off by the disease, that the very name carries terror with it; and so generally has blood-letting in this and in all diseases been denounced by teachers in medical colleges and by their graduates during the last twenty years, that, although the family had great confidence in their physician, yet that he should use this dangerous remedy here, in this generally fatal disease, alarmed them, and they believed death, and not relief and recovery would result. Hence their surprise.

These cases, so successfully treated by the three Conshohocken physicians—not with two or three consulting physicians to help them and share the responsibility, but each one by himself—were of the same kind as those which have carried off hundreds of noble men since Dr. Vinton was lost. Let us fancy now that some of those denouncers of the means used by Drs. Beaver, McKenzie and Highley had had these cases in charge, what would they have done to relieve them, when they were laboring for breath and threatened with suffocation? The first step would have been to have a consultation; then perhaps—what? I can't answer. Possibly they would conclude to wait for the crisis, and, while waiting, to give stimulants—whiskey, etc., to support the patient until the crisis—I mean the living crisis, still two days off, should come; not seeing that the crisis by death was but a few hours away.

I am shocked by the mere thought of the scene. The poor man, helpless and threatened with death, lying before them, his lungs overwhelmed with blood, every vessel distended to its utmost, stretched and thinned until the blood is being forced through their coats and fills the bronchi to the exclusion of all air—as he thus suffocates, what will the reformers do for him? I await their reply.

TREATMENT OF TYPHOID FEVER.[1]

BY S. E. ROBERTSON, M. D.,
NEWARK, N. J.

In discussing the treatment of typhoid fever, it is necessary to indicate what objects we desire to obtain by our efforts. The variety of symptoms is very large. Are our main efforts to be directed to the lowering of the temperature, the checking of the diarrhœa, the quieting of the delirium, the controlling of persistent epistaxis, to allaying an irritable stomach, healing the ulcers, or perhaps, most important of all, to sustaining the vital powers of the patient against the inroads of all or any of the above? If it is true—as it appears to me to be—that typhoid fever is a self-limited disease, the last idea would appear to me to be the principal one in any line of treatment. In ordinary cases the disease runs a course of about three weeks, more or less, in accordance with the number and severity of the complications, irrespective almost of any efforts to the contrary.

Most medical men appear to be satisfied that the cause of the disease is a micro-organism, and the removal of the cause should end the disease. But we do not appear to be able to remove the cause before its allotted period; as the disease still holds the fort for its usual period of three weeks

[1] Read before the Practitioners' Club.

or thereabouts. Others say, reduce the fever, and the patient will rise. But that is apparently beyond our control. The efforts of others are directed against the diarrhœa; but with no better result; and we very often see a severe type of this disease where there is no characteristic diarrhœa.

Our efforts towards shortening the duration of an attack of typhoid fever being futile, let us glance over the histories of a few cases, in order that we may observe what causes tend to produce death: a result that we must strive to prevent, whether the course of the disease is shortened or not. I will give the reports of a few cases only, in order to show the routine followed, and then I will speak of a few of the so-called "specifics."

Case 1. Patrick K., 29 years old, married, laborer, came under observation August 11, 1889. For two weeks before he had complained of pain in his head, legs and back; had also had fever; had drank well-water only. Upon examination I found his pulse 124, his temperature 105° F. He had a dry, coated tongue and tympanites; had had no diarrhœa, and there were no abdominal spots; but he had great thirst, and intense headache. I suspended my diagnosis and gave potassia bromide, grs. xx, every four hours, and antifebrin, grs. v, twice a day for two days. The temperature was 104° F. in the evening of the second day. The patient now had clay-colored stools frequently, and nose-bleed. I diagnosticated typhoid fever, stopped the antifebrin, and continued the bromide as before, with milk and brandy in as large quantities as the patient could take.

August 15 the temperature was 100° F. in the morning, with an evening exacerbation. August 19 the temperature was normal, and for five following days, when the patient's wife gave him a small piece of cake. That night the temperature was 106° F., but in four days it was normal again; and the patient rapidly convalesced.

Case 2. E. J., 27 years old, married, laborer, came under observation August 11, 1889. The patient was so weak that he was not questioned regarding his previous history. Examination disclosed the presence of hypostatic congestion of both lungs, persistent cough, rose-colored spots upon the abdomen, tympanites, a temperature of 105° F., and a pulse of 130. I ordered antifebrin, grs. v, night and morning, also spirits of nitrous ether and liq. ammonii acitatis, f℥i, each every two hours, milk and brandy, and counter-irritation to the chest. August 13, the temperature in the evening was 105°. August 14, it was 103° F. in the evening. August 15, it was 101° at noon, and the pulse 84. I ordered ammonii muriates grs. x, and tr. digitalis ♏ v, every three hours. August 17, the temperature was 106° F. in the afternoon, and I stopped the antifebrin. August 18, the temperature was 103° F. in the morning, and the patient had frequent clayey stools. From this out temperature gradually receded, until August 31, when it became normal and stayed so, the patient being well.

Case 3. L. G., 24 years old, single, came under observation August 11, 1889. The patient stated that he had not been feeling well for ten or twelve days; he had headache, pain in the back and limbs, epistaxis, diarrhœa, light, clay-colored stools, tympanites, dry, furred, brown tongue and rose-colored spots on the abdomen. Diagnosis: typhoid fever. The temperature was 104° F., the pulse 126. I ordered milk-diet and brandy, also carbolic acid, gtt. ii, in glycerine every four hours and cold sponging as required. August 12, the patient has had severe epistaxis; his temperature was 102° F., in the morning. August 15 the temperature was $104\frac{2}{5}°$ in the afternoon. I ordered antifebrin, grs. v, twice a day and free stimulation. August 17 there was no diarrhœa. The patient was delirious, the temperature $104\frac{2}{5}°$, the pulse 160. I ordered tr. digitalis ♏ x; ammon. carb., grs. v, every two hours. August 18 the temperature was $105\frac{4}{5}°$; the pulse could not be counted. August 19 the patient died of exhaustion.

Case 4. M. B., 22 years old, single, laborer, came under observation July 26, 1889. For two weeks before admission he had had pains in the back, legs and head, slight diarrhœa and no appetite. Upon examination he was found to have a temperature of 104° F. and a pulse of 130. July 27 he had severe diarrhœa and nose-bleed, tympanites, a few rose-colored spots on the abdomen, was delirious and violent; his temperature was 104° F. I ordered acid carbolici, gtt. ii, in glycerine every four hours; quiniæ sulphates, grs. v, tod., milk-diet and brandy. There was no change, except gradually lower temperature, until August 7, when the temperature was 100° F. Delirium had ceased, there was slight diarrhœa; and the pulse was 76. August 10 the temperature was 99°, and it kept so for five days, when the patient developed a

small boil on his forehead, and by August 22 the temperature rose to 103½°. The boil was opened, and the temperature gradually sank to normal by August 28, the patient being well.

Case 5. J. R., 19 years old, came under observation August 20, 1889. For two weeks he had had severe headache, pain in the back and limbs, diarrhœa, nose-bleed, high fever and constant vomiting. I diagnosticated typhoid fever and ordered oxalate of cerium, gr. ii, every hour, and what milk and brandy he could retain. For nine days this patient's stomach rejected almost everything given him; but the temperature, which was 104⅗° F., when he was first seen, gradually came down to 101° F., when he began to retain milk and brandy in moderate quantities and his temperature gradually fell to the normal point in ten days more; the diarrhœa stopped and the patient gradually convalesced. During this time his pulse was several times so weak and irregular that it could not be counted.

In the consideration of these cases, it will be noticed that milk and brandy were constantly used in the treatment of each case, and the departure from such a diet (*i. e.*, a liquid diet) was followed by a return of all the severe symptoms, and it is my desire to impress the fact that a strictly liquid diet appears to have a very important bearing upon the treatment of typhoid fever, as well as in all other acute febrile diseases.

In the first case antifebrin for two days, bromide of potash and liquid diet were the only means used; and when the liquid diet was interfered with—slight though the interference was—there was a return of all the symptoms, with a greater degree of severity. Some have extolled antifebrin as a specific in this disease; but in a large number of cases, in which I have seen it used, I have not once seen either a permanent or a prolonged reduction of the temperature; and, I fancy, I have always observed a certain amount of depression, and in several cases, great depression has followed its administration.

In the second case the patient was almost in collapse, and a further trial of the antifebrin was made, combined, however, with a stimulant preparation of ether and ammonia; but the temperature still rose, the antifibrin was stopped, and cold baths, free stimulation and liquid diet were ordered, with a happy result. In this case the antifebrin appeared to have an almost immediate depressing result after each administration of it. In the third case we have a severe typical case of typhoid fever, in which all the remedies mentioned above were tried, as well as one of the recent specifics, carbolic acid; but, notwithstanding all, death ensued. It is but fair to state that this patient, before coming under observation, had been drinking and eating, and living in a way contrary to the recognized laws of health; and the shock was more than his impaired constitution could withstand. In the fourth case, a counterpart of the third case—where quinine was substituted for antifebrin, the patient recovered in the usual time: a strictly liquid diet being insisted upon.

In case V, where the temperature was very high and persistent emesis was the most troublesome symptom, the oxalate of cerium was the only medicine used; fluid diet and full stimulation being carried out as fully as the condition of the stomach would allow.

In the treatment of some fifty odd cases of typhoid fever seen in hospital and private practice, where there occurred five deaths, I have come to place the most confidence in the following routine, varied for special cases: In the second week, which is the time when we are usually called, I prescribe quinine, sulph. gr. v, thrice daily, cold sponging several times a day, milk and brandy as freely as possible. If there is diarrhœa of more than four stools a day, paregoric f℥i is given after each stool; if there is great depression, digitalis and ammonia are given. Fresh air, warm bed-clothes and frequent changing of the bed-clothes are provided for. If there is hemorrhage from the bowels, five drops of turpentine are ordered to be given every hour with opium and absolute quiet. The quinine acts only as a tonic, I think; although it is given by some as a germicide. The sponging produces diaphoresis, and acts also as a tonic when not carried too far. In one hospital where the windows were removed from the fever wards, the mortality was *nil* in eighty cases, and in another fever ward in the same hospital, under the same physicians, the mortality was 22 per cent., showing a decided benefit from the fresh air.

Antipyrin has been greatly praised in typhoid fever, as an antipyretic, nerve sedative and germicide. I have used it in two cases, and found it had a quieting effect; but the range of temperature was not reduced, nor the time of convalescence hastened. Carbolic acid is perhaps more used than any

other antiseptic. I have seen it used extensively, and I must say, I have never observed any change in the condition of any patient when its use has been commenced or stopped. Tincture of iodine has been used alone and with carbolic acid with favorable results. I have not used it—I have used salicylate of soda instead of quinine, and have had about the same results as from quinine; but I think the stomach does not tolerate the salicylate for so long a period as it does the quinine. I have observed considerable irritability of the stomach from the salicylate of soda in typhoid fever. Calomel and bichloride of mercury have been used extensively years ago in this disease; and although they have fallen somewhat into disuse, I observe they are being highly spoken of in this connection in recent articles. Some writers recommend calomel in large doses during the first week of the disease, and in small doses later on: the idea being to get its germicidal virtues after thoroughly emptying the intestines. Bichloride of mercury in very small doses throughout the disease is said by its patrons to lessen the mortality and to decrease the severity of the symptoms. Thallin, boric acid and eucalyptus are also highly spoken of. Cocaine has been recommended by Da Costa as ameliorating the symptoms and hastening convalescence; but there has been urged the objection of its uncertain toxic effects. One writer states that the temperature is increased upon the ingestion of fluids; another takes the reverse as the basis of a long article upon the treatment of fevers generally and of typhoid fever in particular. The use of oxygen would appear to be rational; and it has been used, especially for its effects upon the temperature; while certain writers advise the administration of air containing an excess of nitrogen for the same effect, and probably pure air alone would be beneficial.

Nevin recommends good nursing, removal of irritation, and means to lower excessively high temperatures, with alimentation, as the chief requisites. Austin Flint has recently attracted considerable attention to his vigorous support of the so-called alcoholic treatment, upon physiological grounds alone; and, in such a manner, we could find fair authority for almost any treatment of typhoid fever: bleeding not being excepted. But it appears to me that the treatment of Nevin and Flint combined will show as small a death rate as any other.

PERISCOPE.

Simple Truss for Hernia in Children.

One of the most interesting, and, at the same time, one of the most important subjects in connection with the surgery of childhood, is that of congenital inguinal hernia. At the meeting of the Medical Society of London, held Feb. 3 and reported in the *Medical Press and Circular*, Feb. 12, 1890, Mr. Edmund Owen delivered the third Lettsomian lecture, in which he spoke at length on this subject. Mr. Owen said that at the outset of his remarks he would urge the expediency of regarding the defect not as a pathological entity, but merely as a sign or symptom. Generally it is but the sign of arrested development in connection with the obliteration of the funicular process of the peritoneum; often it is a symptom of some oft repeated and straining expiratory effort, such as that associated with whooping-cough, diarrhœa, chronic constipation, rectal polypus, vesical calculus, or impeded micturition. Therefore, in every case of congenital hernia, the surgeon should make it his first duty to try and discover the cause of the protrusion, and promptly direct his attention thereto. If the only discoverable cause be a patency of the funicular process, the surgeon will help the case by applying a little pressure over the inguinal region, so as to prevent further descent of the bowel and thus give the tubular process the opportunity of completing its obliteration. Mr. Owen said that he recently had had a male infant under his care in whom he had produced an inguinal hernia by applying an appropriate bandage for the treatment of a troublesome umbilical rupture. When first seen by Mr. Owen, the infant was apparently sound in the inguinal region, and there was no history of his having had, at any time, any other protrusion than that of the navel, which, by the by, demanded unusually firm repression; but when this, at last, was firmly imprisoned, the bowel escaped by the scrotum. Mr. Owen does not remember having met with any other case in which a second protrusion had been brought about in this manner. Doubtless, as development proceeded, and the abdomen obtained its proper proportion, there would be ample accommodation for all the viscera.

At an early period of intra-uterine life the abdominal cavity is for this purpose alto-

gether inadequate, and that, being open in the front, the viscera remain for a considerable time spread upon the front of its anterior wall, and that afterwards, as growth increases, space is arranged for their reception within the embrace of the abdominal walls. After birth if the three chief apertures are not securely closed, forced expulsive efforts are apt to drive a knuckle of bowel, or something more from the interior of the general cavity.

With the view of diminishing the risk of violent expiratory efforts, the surgeon will try to arrange that the infant takes enough food to prevent his crying for more, and yet not enough to make himself strain with vomiting. He will also keep the infant as much as possible in an horizontal position.

For tender infants spring-trusses are ill-suited ; the necessary pressure may be usually obtained by employing a skein of wool after the manner described by Mr. Lund and originally suggested, I believe, by the late Mr. Coates, of Salisbury : A folded skein of Berlin wool should have the loop laid over the emptied inguinal canal, the ends being carried across the abdomen above the crest of the ilium, of the sound side, across the back, and then forward along the crest of the ilium of the ruptured side. The ends are then passed through the inguinal loop, and carried backward round the inner side of the thigh, and across the buttock, to be firmly secured to that part of the skein which is already just above the great trochanter. The infant can be washed with this truss on, a fresh one being subsequently applied. Mr. Owen said that his experience with this simple apparatus is that the monthly nurse, or child's nurse, quickly sees its value, and interests herself in applying the skein ; that there is no fear of its making the child sore, or of hurting him, and that with average skill and care, its compression can be directed in so exact and efficient a manner as in time to produce effacement of the weakness.

Supposing that there is a tight prepuce, the indication for treatment is obvious. If, after the most careful inquiries, no cause for the hernia can be discovered, and if the use of the skein of worsted proves disappointing, a truss must be carefully chosen and adjusted. If the hernia be troublesome the compression should be enacted by night as well as by day, for it is great matter never to give the bowel the chance of coming down. As a rule, the truss which the instrument maker chooses for the child is needlessly strong in the spring, and the skin becoming red and sore all pressure has to be remitted for a while. This is, of course, most unfortunate. Occasionally I have seen an extensive ulcer marking the site at which the pad pressed. The band and pad of every truss should be covered with a soft piece of linen, and the area of skin which is pressed upon, should be washed and dried with extra attention, and then dusted with violet powder.

It is a matter of almost daily experience that with the exercise of due care in the choice of the truss, and with patience in its subsequent employment, the child may be expected to "grow out of" his trouble. It will be impossible to say at the outset when the cure will be effected. Many children lose the defect within the first year ; in some the treatment has to be carried on through several years, and in others the cure does not arrive till puberty. Lastly, there are some cases in which, though manhood has been reached, the truss must not be discarded.

Occasionally one sees a child wearing a truss where there is absolutely no need for pressure in the inguinal region, and where its employment must therefore be harmful ; when, the funicular process of peritoneum having been obliterated, the risk of descent of the bowel has become a thing of the past. And, further, on rare occasions a child is found wearing a truss who has not, and who never has had, any inguinal hernia whatever.

The class of cases in which this last error is most likely to be committed is that in which the peritoneal process has been occluded at the internal abdominal end and also over the lower part of the cord, but in which the intermediate portion is dilated into an encysted hydrocele. It is by no means easy in some of these cases to make up one's mind as to the nature of the rounded tumor, especially if it be lodged within the inguinal canal, and, therefore, beyond the reach of examination by a lighted taper. But the fact of the tumor remaining of the same size day after day, and of its being irreducible and hard, without the chill exhibiting symptoms of strangulation, is generally sufficient in the way of diagnosis. In such a case the introduction of the hollow needle of a hypodermic syringe resolves the tumor and the doubt.

Impotence.

Impotence, or, as it is sometimes called, sterility in the male, may be classified under two heads: aspermatism and azoöspermism. In aspermatism no ejection of seminal fluid occurs during coition. This may be because no semen finds its way into the urethra, or it may be because its ejection from the urethra has, in some way, been hindered. Four varieties of aspermatism are known: First, those arising from defects of the ejaculatory ducts, severe urethral stricture, or phimosis. Second, atonic spermatism, resulting from an inexcitability of the ejaculatory centre. In such cases there is a general neurasthenia, and the cells of the ejaculatory centre are weakened and incapable of work. Third, anæsthetic aspermatism, due to a loss of sensibility of the penis, so that for want of peripheric reflex an injection of semen is rendered impossible. The fourth cause of aspermatism is referred to a psychical origin; the hypothesis being that a lesion in the brain itself prevents the seminal emission.

In azoöspermism there is an injection of semen during coition, but it is unfruitful. This is due to an entire absence of spermatozoæ, or, if present, they are either dead or possess a vitality insufficient for fecundation. Among the causes of such a condition may be named the following: cachexia, bilateral anorchism, or absence of the testicle, carcinomatous degeneration of the testicles, tuberculosis, syphilis, traumatism, and severe atrophy of the testicles. An absence of spermatozoæ in the semen may also be due to a closure of both seminal ducts, this condition frequently follows after double gonorrhœal epididyemitis. Finally, severe cystitis may cause the death of the spermatozoæ immediately after their ejection.

The importance of the foregoing explanation is evident from the history of the following case, which was reported by Dr. E. Caspar, of Berlin, to the Berlin Medical Society, Jan. 13, and quoted in the *Wiener Med. Presse*, Feb. 2, 1890.

The patient was a man 32 years old who consulted Dr. Caspar in February, 1888, about the possible causes of his unfruitful marriage. The patient's wife had already been examined by a gynecologist, who had failed to find any cause for her childlessness. The patient gave a history of an attack of gonorrhœa, eight years before, which had resulted in cystitis, left epididymitis and urethral stricture. Otherwise the patient had always enjoyed good health. There was no history of syphilis. The man had been married for two years; he had practiced sexual intercourse with regularity, and coition was always completed by an emission of semen, but, as yet, his wife had not become pregnant. On examination it was found that the patient's genital organs were well developed and his urine normal; his heart and lungs were also found to be sound. All the lymphatic glands, however, were considerably enlarged, especially those of the inguinal region; the posterior wall of the pharynx was also observed to be inflamed, dry and shining, and a small irregular shaped ulcer was found on the left tonsil. A diagnosis of secondary syphilis was given. Dr. Caspar then examined the freshly emitted semen of the patient and was unable to discover any trace of spermatozoæ in it. The impotency was therefore due to azoöspermism. As the above mentioned causes for azoösperism were not applicable in this case, it was concluded that the functional disability of the generative glands was due to the presence of the specific disease. The subsequent result of an active anti-syphilitic treatment proved the correctness of this theory. The patient was put on a course of mercury and iodides.

Three months later the symptoms of syphilis were found to have almost entirely disappeared. The semen was again examined, and a few sluggishly moving spermatozoæ discovered. The azoöspermism had, therefore, changed to an "oligozoösperism." The administration of iodides was stopped, and when, a month later, the semen was again examined the number of spermatozoæ was found to have greatly increased and their activity was normal. The patient's wife now soon became pregnant. The child, when born, showed symptoms of hereditary syphilis.

It is evident, from the above case, that the functional power of the testicle may be impaired by the syphilitic poison, and azoösperism be the result. The same condition has been observed to be brought about by the habitual use of morphine, and, in the latter cases the spermatozoæ again appear in the semen, as soon as the drug is discontinued.

According to Lewin, spermatozoæ will be found to be absent from the semen of fifty per cent. of syphilitic, although otherwise healthy, men. Further researches in this

line may tend to make the therapeutics of impotency of greater efficacy than they have heretofore been.

Injections in Acute Gonorrhœa.

The *Lancet*, Feb. 15, 1890, states that Dr. L. Friedheim, assistant in the clinic of Professor Neisser at Breslau, who has made a large number of observations with several drugs, such as zinc, lead, bismuth, tannin, various preparations of mercury, permanganate of potash, creolin, etc., to test their astringent effect as well as their capacity for destroying gonococci, is equally dissatisfied with all the usual drugs. They all had either no permanent effect in destroying gonococci, or they irritated the mucous membrane to such an extent that their administration had to be stopped. Nitrate of silver alone acted quite satisfactorily. Dr. Friedheim reports on 318 cases treated with this drug, 237 of which proved its antibacterial effect satisfactorily. Unfavorable results were chiefly obtained with out-patients who lived in unsatisfactory circumstances. The following is the method pursued in Professor Neisser's clinic:—Every acute gonorrhœa is immediately treated with an injection of nitrate of silver of the strength of from 1 in 4,000 to 1 in 2,000. The discharge generally increases at first, becoming thicker and more purulent, but very soon decreases and becomes thinner, whiter and more epithelial. The gonococci decreases in a remarkably short time, and sometimes entirely disappear in a few days. The injections are first administered from four to six times a day, and are then reduced to one or two in the twenty-four hours, when at the same time a mild astringent like zinc or boric acid is injected; but even after entire cessation of the discharge, the nitrate of silver is still injected once a day for many weeks. The proper regimen must be followed for an equally long time. The injections are administered even when complications occur, especially epididymitis.

Need of Examining Boards.

The *Northwestern Lancet*, February 15, contains a number of answers made by graduates of medical schools to questions of the Minnesota Medical Examining Board. They confirm the demonstration of other Examining Boards that State examinations are needed to protect the community against the ignorance of men who seem to have no trouble in getting diplomas. Some of the answers follow:

"Symptoms of odema of the glottis are that the patient feels husky and has sore throat. I would amputate it if necessary. I would do the operation within three or four months, if it was a bad case."

"The dose of morphia sulph. for a child of five years, hypodermically, would be one-fourth grain, and if that doesn't give relief, I would give one-half grain."

"The dose of antipyrin for a child five years old is fifteen grains every three hours."

"The pulmonary artery is a branch from the great arto, fully supplying the lungs with arterial blood."

"The kidney is a muscular formation, in shape oblong, color quite dark, weight about one pound to one and a half, but may vary considerable."

"Parts severed in amputation at upper third of thigh—just avoiding the insertion of the glutei musels, passing through the Taylor's musel, periostum and femer."

"The sympathetic system is composed of all the filament of nerves that start from the spinal cord, and are distributed to all parts of the system, especially the brain. The cervical portion ramifies the encephalon in general. The dorsal portion ramifies the anus."

"Extra Uterine pregnancy may be a fungoid groth or tumor fibroid in its character or any extra groth in the uttrous would be called extra uterine pregnancy."

"Trismus neynatorum—a peculiar trouble of the eye, generally congenital, falling of the lids giving a unnatural look to the ordinary face of a child."

Q. "Give the distinctive histological features of carcinoma." A. "Carcinoma will show a general dropsical condition. Transparent condition of all the fluids except the urine which may show considerable deposit, scanty and hot. The patient's puls heavy, large, does not care to move."

"Tubercle of lung is supposed cause of consumption and the one generally advocated, and preventive treatment is any that will burn up them or destroy them I am a believer in alcohol but the why and its action I am unable to give."

Q. "How would you tell Sulph. Morphia from Sulph. Quinia?" A. "Sulph. Quinia is white flaky glistening. Has a metallic look. Tastes bitter. Never saw any pure Sulph. Morphia in my life. Have no use for either."

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LEPROSY AND LEPERS.

Within the past few years we have frequently had occasion to refer in the REPORTER, both editorially and otherwise, to the subject of leprosy, and have especially discussed the question of its asserted contagiousness. In the issue for November 9, 1889, we maintained that this disease ought not to be spoken of as contagious in the ordinary acceptation of the term, although admitting that very possibly it may be communicable from one individual to another under certain circumstances. At that time we also spoke of the opinion held by some pathologists that leprosy is a very contagious disease. The dread of this disease has agitated the minds of many of the profession, both in this country and in England, and it has been spread among the people to an extent which we regard as to be much regretted. In the latter part of 1887 it was discovered that two lepers, a woman and her daughter, were in the city of Philadelphia, and notwithstanding the suggestions of medical men who knew something about leprosy, they were quickly dispatched to the Municipal Hospital, where they were isolated and treated with a caution more extreme than if they had had small-pox. After guarding the patients with exaggerated and absurd vigilance the authorities began to bestir themselves as how best to get rid of them. The Captain of the ship which had brought them to the United States was at last induced to take them away again; and the authorities so far abandoned their previous position in regard to the contagiousness of the disease as to send the patients to the port where the ship lay, in an ordinary passenger train, filled with other unsuspecting travelers, from whose scrutiny the patients were hidden by thick veils.

Very recently, the old fear has once more seized the health authorities of Philadelphia, and its people, and the daily papers have announced that the bacillus of leprosy is at large among us again. This time the unfortunate victim is a Chinese laundryman, who, being attacked with facial erysipelas and forsaken by his countrymen, was removed to the Philadelphia Hospital for treatment. Here the possibility that the man was a leper was recognized, and microscopical sections of the suspected lesions were examined day after day until the bacillus of leprosy was found. As soon as this was known, the man was hurried off with all speed to the Municipal Hospital for contagious diseases.

The interest of the REPORTER being aroused, we sent a representative—who had resided in China for several years, and had had opportunity to see a great deal of the disease—to the Municipal Hospital to investigate the case. Any one who has lived in China knows that in that country leprosy is very common, and that it is diagnosticated

without any search for the bacillus, since the disease, when at all advanced, may be recognized with great ease. On the streets in Chinese towns, lepers are more common than blind men are here. They come into the shops and grovel on the floor before the shoppers, beating tin cans to attract attention, and exhibiting their deformities. They are licensed paupers, and the shopkeepers have no right to order them out without giving them some alms. So a resident in China, especially if he is a frequent visitor to the Chinese towns and does not confine himself to the foreign settlements, soon finds himself familiar with lepers and leprosy. Through the courtesy of the officers of the Hospital our representative was at once shown the Philadelphia patient. After traversing long halls and going up several flights of stairs and through a number of doors, each of which was closed with scrupulous caution, probably to guard against the exit of the microbe, the ward in which the leper was confined was finally reached. The nurse in charge was summoned, and, to our representative's amusement, donned a huge pair of rubber gloves before going near the patient.

A slight examination was quite sufficient to show that the case was one of well-marked and fairly developed leprosy, of the type usually met with in China. The hands and feet of the man were principally affected. The left hand, according to the patient's own statement, had been contracted by the disease for a year. The feet had been affected for a "very long time." The Chinaman said he had been in the country for fifteen years; and if so, it is very probable that he came here a leper. Had it not been for the attack of facial erysipelas, and the loss of the use of his feet, he would be still at work in his laundry as he has been during all these years without doing anybody harm.

The facts of the present case confirm our opinions as to the impropriety and folly of speaking or acting as if leprosy was a contagious disease—in the usual acceptation of this term.

The unwarranted fear which has governed the authorities of Philadelphia, and a few other cities of the United States, upon the discovery of isolated cases of leprosy furnishes a sad commentary upon the state of knowledge in regard to leprosy which prevails in the ranks of the medical profession in this country. We have done what we could in the columns of the REPORTER to present to the profession what is known, as well as what is thought, by those who are most familiar with the disorder. We have not withheld the information that a number of distinguished observers in various countries speak of leprosy as a contagious disease; but we have repeatedly stated what a careful study of all the evidence seems to us to show plainly—that is, that if contagious at all, leprosy is so in such a slight degree that no one in this country need be much afraid of it, and that such extreme precautions as have been practiced at times by the health authorities of American cities are unjust to the subjects of the disease and injurious to the community.

REFORM IN MEDICAL EDUCATION AND ITS OPPONENTS.

Our wide-awake and plain-speaking contemporary, the *Medical Standard*, of Chicago, April, 1890, says: "A demagogic attempt is now being made to repeal a law requiring preliminary examination of persons preparing to enter upon the study of medicine by the regents of the New York State University. Dr. Austin Flint advocates the repeal of the law for the following reasons:

"The law affects the four medical colleges in New York and Brooklyn. Out of 2,318 students and 627 graduates in the entire State in 1889, these colleges had 1,921 students and 528 graduates, or about 80 per cent. of the whole number. Yet the bill requiring preliminary examinations was passed without their knowledge or consent. It

works especial injury to non-residents who come to New York to complete studies begun elsewhere. The non-resident students in the metropolitan colleges number 942, or about one-half of the whole; in the country colleges only 31. In the city colleges last year 293 non-resident students were also graduated; so that the continuance of the preliminary examination law is likely to destroy New York's prestige as a centre of medical education and drive students to Philadelphia. The New York students now spend annually $1,000,000 in the city, and support hundreds of families about Bellevue Hospital.

"Such an attempt to enlist local jealousies against a law, which every educated man cannot fail to see is beneficial to profession and public alike, is decidedly inconsistent with the ultra zeal Dr. A. Flint has avowed on behalf of medical orthodoxy. The New York county medical societies which had the law enacted, will doubtless prevent its repeal. In any event, this action of a leading light of the American Medical Association deserves the attention of that body on professional grounds."

In the same connection we note that the *Journal of the American Medical Association*, April 12, contains a very vigorous editorial on the same subject, which will hardly be enjoyed by those who prefer selfish and local interests to the advance of reforms. On the other hand, those who are laboring for the elevation of the standard of medical education, and of the medical profession in the United States, and especially those who have shown a willingness to sacrifice something in this good cause, will rejoice to see that almost all over the country the supporters of the cause are multiplying, and its opposers are losing ground.

Every American city in which the standard of medical education has been, or is being raised would be glad to have the co-operation of the New York medical schools, and hope to have it before long, notwithstanding such unfortunate utterances as have recently come from Professor Flint. Meanwhile the reform is advancing, and it is only a question of time when it will prevail over all the opposition which has been made to it.

STRANGE PICTURE OF TYPHOID FEVER IN THE UNITED STATES.

At a meeting of the Medical Society of Berlin, held Feb. 26, and reported in the *Bulletin Médical*, March 12, 1890, Dr. Kronecker read a paper on the difference in the manifestations of typhoid fever in the United States and in Europe.

Having passed a year, he said, in the German Hospital of New York City, he had observed marked differences in the evolution of various infectious diseases, but especially in typhoid fever. He then gave the following remarkable account of his observations. In New York, the onset of typhoid, he said, is sudden and without any prodromic period. The patient complains of headache and lumbago; while vertigo, vomiting, and high fever are also present, and frequently diarrhœa occurs within the first twenty-four hours. In short, within a few days, the patient presents the typical picture of typhoid fever. The temperature is also much higher than in European typhoids; temperatures of 106.5° to 107.2° F. being not rare. Some patients, he said, recover after a period of illness, during which the temperature never sinks below 104°.

Defervescence, said Dr. Kronecker, seldom occurs until the twenty-eighth day. In some cases the type of fever is distinctly intermittent. The pulmonary complications observed are most serious; adynamia and coma are very frequent complications. The delirium is frequently of a violent character. This is explainable, he says, by the alcoholic habits of the population; and the frequent occurrence of collapse and the necessity for the frequent administration of excitants may also be attributed to the same cause. Baths, if at all employed, he says, must be used with great caution. The eruption of typhoid

spots is generally so abundant that the cases might be easily mistaken for exanthematous typhus fever. Intestinal hemorrhages are rare; but when they occur they are excessive.

It is not surprising that such a report should be deemed worthy of a full and prompt presentation by the correspondent of a French medical journal; but we can hardly understand how it could have been made by any careful observer. It is possible that, when Dr. Kronecker was at the German Hospital in New York, he found such typhoid fever there; but to present it as the common type of typhoid fever was a great mistake. We would be astonished to find it the type even in the German Hospital and it certainly is not the type throughout the country.

Dr. Kronecker's representation of the type of typhoid fever in the United States being so erroneous, it is, of course, not worth while to discuss his explanations. These, as well as the premises upon which they rest, are alike examples of the danger of loose observation and hasty generalization.

THE GRIPPE AS A PNEUMOGASTRIC NEUROSIS.

The universal attention which has been given to the recent epidemic serves to emphasize two things: First, the affinity of the poison, or cause of whatever sort, for the nervous system; second, the frequency of pulmonary, cardiac, gastric and intestinal complications. The symptoms which are most characteristic in the grippe are: A sudden and unaccountable appearance of severe headache, pain in the neck, spine, legs and feet; a tired and weary feeling throughout the whole body, accompanied by chilliness, fever, dizziness, staggering and inability to stand; an indifferent and listless state, as if the patient were passing through a siege of great nervous prostration; a laborious respiration associated with bronchitis, pneumonia, pulmonary œdema, etc., but out of all proportion to that which would be expected from the amount of lung lesion present; a frequently and irregularly acting heart; tachycardia; violent abdominal pain; vomiting and severe diarrhœa; sudden collapse; and death from respiratory and cardiac failure.

It is interesting to observe in this relation that M. Huchard (*Revue générale de Clinique et de Thérapeutique*, January 16, 1890) connects all these various phenomena with the theory that the poison of the influenza explodes on the central nervous system and peripheral nerves, but attacks the pneumogastric nerve most violently, and through its pulmonary branch produces pneumonia, hemoptoic pulmonary congestion, pulmonary œdema, bronchial paralysis, and a pertussis-like cough; through its cardiac branch, syncope, intermittence, bradycardia, tachycardia, anginiform disturbance and sudden death; and, through its gastric and intestinal branch, vomiting and various gastro-intestinal disorders.

This theory is also maintained by the eminent Dr. Graves, of Dublin, and by M. Vovart, of Bordeaux, and is in entire accord with our knowledge concerning the influence which vagus disturbances exercise over the pulmonary organs. Section or irritation of these nerves produces pulmonary hemorrhage, œdema and pneumonia in animals and in man. Quite recently this fact has also been brought conspicuously before the profession by the writings of Dr. Thomas J. Mays, of this city, who holds to the view that not only bronchitis, pulmonary œdema and pneumonia are the legitimate consequences of pneumogastric disease, but that pulmonary consumption owes its existence to the same source.

We believe that these investigations in regard to the nature of influenza have an important bearing on the future etiology and pathology of pulmonary and cardiac diseases; and in these days when the cause of every disease is sought in the vortex of bacillary infection, it is refreshing to find that

efforts are made to trace an anatomical relation in disease, which in itself serves as a key to, and points out the natural sequences of, morbid changes. This is the true aim of scientific investigation, and medicine will advance only when this principle is fully recognized and put into practice.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

TRANSACTIONS OF THE MEDICAL ASSOCIATION OF THE STATE OF MISSOURI. Thirty-second Annual Meeting, Springfield, Mo., May 21. 8vo, pp. 218. St. Louis: Ev. E. Carreras, 1889.

The Transactions of the Missouri Medical Association deserve more than a passing notice. The character of the essays, of which there are twenty-two, is far above the average, and speaks well for the scientific standing of the profession in Missouri. We would fain review the merits of each essay; but lack of space forbids. The papers on the subjects, Antiseptic Medicine, by Dr. E. W. Schauffler, of Kansas City, and Comparative Tuberculosis, by Dr. Paul Paquin, of Columbia, are of great interest and well up to date; while Dr. A. H. Ohmann-Dumesnil's paper on Alopecia Areata, and Dr. Robert Barclay's paper on Precepts of Aural Practice, are of great practical value. The results reached by Dr. R. E. Young, of Nevada, in his paper on the Causes of Insanity, are based on an investigation of 21,190 cases of insanity. Ill-health, intemperance, the puerperal condition, uterine disease, epilepsy, heredity, menopause and masturbation were found to be the principal physical causes of insanity; while domestic troubles, emotional excitement, religious excitement, financial trouble and grief were found to be the chief moral causes. Out of 21,190 cases of insanity, 9,858 resulted from physical causes, and 4,611 from moral cause; while in 6,721 cases the origin of the disease could not be determined.

A paper which shows very careful study, and is of great scientific interest, is the one by Dr. L. Bremer, of St. Louis, on Traumatic Neurosis, or Railway Spine. The Association may truly be proud of its work, and the essayists complimented upon their admirable endeavors.

THE LAW OF POPULATION. By Annie Besant. Thirty-fourth thousand. 8vo, Paper cover, pp. 47. Valley Falls, Kansas: Fair Play Publishing Co., 1889. Price, 15 cents; with steel portrait of Mrs. Besant, 30 cents.

Mrs. Besant is known as a most outspoken advocate of the propriety of limiting the number of children in families. This she regards not only as a justifiable course in the marital relation, but as a duty when too many children may mean serious embarrassment in their development, training or support during their minority. In the little book before us—which has had a very large sale in Great Britain and in this country—she not only defends the view stated above but describes various methods of carrying it into practical effect.

The members of the medical profession are not all of one mind in regard to the rightness of the opinion held by Mrs. Besant; but any one of them who care to do her the justice of hearing the reasons why she holds it, will find them stated plainly and with perfect propriety in the little book under notice. They may not be convinced, but they will certainly, by reading the book, get a truer idea of her motives than they are likely to get if they limit their reading to the works of her critics.

THE YEAR BOOK OF TREATMENT FOR 1890. Small 8vo, pp. viii, 324. Philadelphia: Lea Brothers & Co., 1890. Price, $1.00.

This little book fully maintains the reputation of its predecessor for reliability and utility. There are many books on the market which attempt—or pretend to attempt—to give a summary of medical progress from year to year; but there is none which in so small a compass gives so good an idea of it as does this excellent little volume.

Literary Notes.

—Beginning with the issue for March, 1890, the *Annals of Gynæcology*, formerly published in Boston, and edited by Dr. E. W. Cushing, was enlarged and improved, and a Department of Pædiatry added, under the editorship of Dr. Louis Starr, of Philadelphia.

The journal is now printed by the University of Pennsylvania Press, Philadelphia, under the name of the *Annals of Gynæcology and Pædiatry*.

—The *Sunday-School Times*, March 29, 1890, contains an article by the Right Hon. W. E. Gladstone, which is the first of a series of articles on the Bible, from his pen. These papers are, by special arrangement with the writer, to appear on the same day in the *Sunday-School Times* in this country, and in *Good Words* in London.

—It is stated that the *Centralblatt fur Nervenheilkunde*, which was discontinued last year, will appear again in April in an enlarged form, under the provisional editorship of Dr. Kurella, of Allenberg, East Prussia.

—With one or two exceptions Spanish medical journals seem to have rather a frail hold on life. No fewer than three Spanish medical journals, the *Medicina Pratica*, the *Revista Cientifica*, and the *Archivos de Medicina y Cirugia de los Ninos*, have come to a premature end since the beginning of 1890, but Drs. Benito Alcina and J. Luis Höhr, of Cadiz, have just brought out the first number of a new Spanish periodical, entitled *La Revista Medico-Quirurgica*.

—*Scribner's Magazine* for April has for its frontispiece an admirable engraving from a painting, made for this periodical by the English artist, J. R. Weguelin, to illustrate an ode of Horace. Other Horatian odes will be illustrated by the same artist in succeeding numbers. This issue also contains the beginning of a notable series on "The Rights of the Citizen;" the last of the Electric Series on the Railway of to-day; an unconventional article of travel describing a journey across the Syrian Desert, besides other interesting articles.

NOTES AND COMMENTS.

Surgeons of the Confederate Army.

At the request of Professor Joseph Jones we publish the following call:

OFFICE OF THE SURGEON-GENERAL OF THE UNITED CONFEDERATE VETERANS,
156 Washington Avenue,
New Orleans, La., April 9, 1890.

TO THE SURVIVORS OF THE MEDICAL CORPS OF THE CONFEDERATE STATES ARMY.

Comrades: The surrender of the Army of Northern Virginia on this day twenty-five years ago, practically ended the struggle for the independence of the Southern States, and during this quarter of a century, death has thinned our ranks and our corps can now oppose but a broken line in the great struggle against human suffering, disease and death.

S. B. Moore, Surgeon-General of the Confederate Army, is dead; Surgeons L. Guild, A. J. Foard, J. H. Berrien, J. T. Darby, W. A. Carrington, F. A. Ramsey, Samuel Choppin, R. J. Breckenridge, E. N. Covey, E. S. Gilliard, E. A. Flewellen, A. N. Tally, Paul F. Eve, O. F. Manson, Louis D. Ford, Habersham James Bolton and a host of other medical officers of the Confederate States Army, all are dead.

The Association of the United Confederate Veterans, the objects of which are historical, social and benevolent, was formed in New Orleans, in 1888.

Our illustrious Commanding General, John B. Gordon, Governor of Georgia, has ordered the United Confederate Veterans to assemble in Chattanooga, Tenn., on July 2, 1890. It is earnestly hoped that every surviving member of the Medical Corps of the Confederate Army will meet us upon this important occasion and promote, by his presence and his counsels, the sacred interests of the Association of the United Confederate Veterans. It is of the greatest importance to the future historians, and also to the honor and welfare of the medical profession in the South, that careful records should be furnished the Surgeon-General of the United Confederate Veterans, embracing the following data:

1. Name, age, nativity, date of commission in the Confederate States Army, nature and length of service of each and every member of the Medical Corps of the Confederate States Army.

2. Obituary notices and records of all deceased members of the Medical Corps of the Confederate Army.

3. The titles and copies of all field and hospital reports of the Medical Corps of the Confederate Army.

4. Titles and copies of all published and unpublished reports, relating to Military Surgery, and diseases of Armies, Camps, Hospitals and Prisons.

The object proposed to be accomplished by the Surgeon-General of the United Confederate Veterans is the collection, classification, preservation and final publication of all the documents and facts bearing upon the history and labors of the Medical Corps of the Confederate States Army during the Civil War, 1861–1865. Everything which relates to this critical period of our national history which shall illustrate the patriotic and self-sacrificing and scientific labors of the Medical Corps of the Confederate States Army, and which shall vindicate the truth of history, should be industriously collated, filed and finally published. It is believed that invaluable documents are scattered over the whole land in the hands of the survivors of the Civil War of 1861–1865, which will form material for correct delineation of the Medical History of the Corps which played so important a part in the great historic drama. Death is daily thinning our ranks, whilst time is laying its heavy hand upon the heads of those whose hair is already whitening with the advance of years and the burden of care.

No delay, fellow-comrades, should be suffered in the collection and preservation of these precious documents. This task of collection of all documents, cases, facts relating to the Medical History of the Confederate Army invites the immediate attention and co-operation of his honored comrades and beloved compatriots throughout the South.

Respectfully, your obedient servant,
JOSEPH JONES, M. D.,
Surgeon-General
United Confederate Veterans.

Phenacetine in Whooping-Cough and Bronchitis.

If there is any remedy which will control a disease in a few days, which, if left to run its natural course, would last an average of ten weeks, it may be safely said that in one

disease at least science has accomplished something. Who has not felt, as he has seen the victim of whooping-cough struggling in its convulsive paroxysms, with its face purple, its eyes bloodshot, and its hands wildly thrown about in agony, the poverty of his art and his science for any relief it could bring to his patient. Scores of remedies have been introduced as specifics, and yet none have been more than partially successful. Possibly the new remedy, phenacetine, may share the fate of its predecessors, and yet we have seen such wonderful results from it in the catarrhal and spasmodic stages of whooping-cough, in the teasing and spasmodic coughs of bronchitis and laryngitis, we are led to hope that in this class of troubles it will yet rival quinine in its own specific field.

In a typical case of whooping-cough in a child eight months old, which had passed through its catarrhal stage and was well on in the second or convulsive stage, the paroxysms coming on every hour of a very violent character, the action of the drug was almost magical. Under the influence of grain and a half doses every three hours, the paroxysms in three or four days were reduced to half a dozen light ones during the twenty-four hours, and in a week had entirely disappeared. Another case was when the attack had not fairly entered the second stage, and yet the exposure of the child and the peculiarity of the symptoms left no doubt as to the character of the disease. In three days the cough had very nearly disappeared under the influence of two-grain doses of the drug every four hours, and in a week's time he was able to return to school. In the schoolmate from whom the disease was contracted, the disease was two months in running its course. In both of these cases the vomiting speedily ceased and the appetite returned. Many other cases occur to us as we write, but the ones quoted above were typical, and will suffice to illustrate the prompt action of the remedy. A lady of middle age was attacked with a sharp pharyngitis, the inflammation, as it was relieved in the pharynx, extending down and involving the larynx and upper bronchial tubes. The expectoration was bloody and purulent, and the cough frequent and painful. In addition to the usual medication five-grain doses of phenacetine was given at first every three hours, and as the cough subsided, every four or six hours. The effect was immediate; with the first dose the whole nervous system was quieted, the cough became less frequent, the temperature diminished, and in a few hours the patient fell into a quiet sleep. The improvement was rapid. There is no doubt the drug produces a very marked effect in relieving the irritability of the nervous system, and acting especially upon the vaso-moter nerves, controls to a certain extent the circulation without any dangerously depressing action upon the heart. As an intercurrent remedy we have reason to believe that in many cases it will supersede opium and its alkaloids and the class of hypnotics of which chloral is the type, because it not only does not prevent, but aids by its quieting power, the specific action of other drugs. We have been particularly pleased with the action of phenacetine in the epidemic of grippe through which we have just passed. In connection with other indicated remedies it has been, in our hands, of very great service.—*N. Y. Medical Times*, April, 1890.

Case of Alleged Hydrophobia.

Dr. William Carson reported at a meeting of the Cincinnati Medical Society, December 3, 1889, as reported in the Cincinnati *Lancet and Clinic*, March 22, 1890, a case of so-called hydrophobia. The diagnosis was suggested by the language of the patient. The history is not complete, for there was no *post-mortem* examination. The subject was an American, eighteen years old, single, a hard drinker. He left home three weeks before his death, and had since been exposed to the weather; had had poor food, irregularly partaken of. He had a sore throat for about a week. About one month before his death he was bitten by a dog. There was no pain in his throat when he was admitted to the hospital. His pulse was 110, his temperature 100.6.° The condition of the urine not known. He was poorly developed; his pupils reacted to the light readily. The left tonsil was inflamed. Dr. Carson ordered salicylate of soda. Delirium came on that afternoon. There were illusions and delusions. He was given stimulants. He said he could not swallow. The urine was then bloody and small in amount. He died that day. There was no special excitement at the examination. The exposure, his want of food, etc., were sufficient to account for his condition. Dr. Carson had before reported cases of nephritis following

tonsillitis. The habit of hard drinking followed for years might develop a nephritis. There was no such dysphagia as could not be explained by a local throat trouble, and no more maniacal excitement than could have been produced by acute alcoholism and nephritis.

Dr. Wm. L. Mussey said that this case reminded him of a case which came to the hospital during his residence there. The patient was a boy ten years of age, and was brought by his father. According to two physicians and the newspapers he had undoubted hydrophobia. The boy was an only child, and had been spoiled by his father and grandmother. It was about the time of the starting of Pasteur's laboratory. The boy was bitten by a cat. He wanted to go to the theatre and was forbidden to do so. The hydrophobia developed that night. When he was brought to the hospital he mewed, scratched, and bit in imitation of a cat. He continued this for a few hours, when the electric brush was applied. There was no further repetition of the symptoms of hydrophobia for several days. The attack then came on again, the electric brush was again applied vigorously, and the patient was shortly discharged cured.

Dr. J. A. Thompson said that in this connection the observation of a dog fancier would be of interest. He was of the opinion that the majority of cases of hydrophobic convulsions in the dog were due to uremic convulsions.

Powdered Milk.

The *American Analyst*, March 6, 1890, quotes from the *American Dairyman* the following in regard to a proposed substitute for milk.

The idea of reducing cows' milk to a dry powder, and shipping it in this condition all over the world seems to have originated with Dr. Krueger, a Swiss savant, and under his management a company was organized to make milk powder in Switzerland. It is claimed that milk in this form is much better than canned or condensed milk; for one reason, it has no sugar in it. It is well known that condensed milk cannot be used in many departments of cooking on account of the sugar, and this also makes it objectionable for use with very young children, not that the sugar itself is injurious to the babies, for it is always put into their milk, we believe, but it is better that this sugar be put in fresh at the time of preparing milk for the child. How far this powdered milk will answer these objections remains to be seen. One thing is certain, the powder will be much better for transportation and more handy to have in the house than either plain or condensed milk, provided it is a success. It looks somewhat dubious as a complete substitute for plain milk, not only on account of necessary expenses, but we do not find any kind of food capable of being thoroughly dried and afterwards made over with water so as to closely resemble the original article, and we never expect to see it done with cows' milk. Nature has a way of mingling these things that thus far man has not been able to closely imitate.

Dislocation of both Shoulders.

Mr. Alex. Milne, of Dewsbury, England, in the *Lancet*, Feb. 22, 1890, reports a case of dislocation of both shoulders. The patient, a man aged sixty, employed in the construction of bridges, was brought to the infirmary suffering from subcoracoid dislocation of both shoulders. The injury had been produced by his falling down a distance of about ten feet between the scaffolding and the bridge in course of construction. Both his arms, stretched above his head, were suddenly caught in his descent, and the jerk had been sufficient to dislocate both shoulders. According to his statement, the right shoulder had been dislocated fourteen years previously, and the left one six years before, and in both cases the accident had happened in precisely the same way as in the last instance.

Experimental Tetanus.

At the meeting of the Medical Society of Berlin, held Feb. 5, 1890, Dr. Weyl showed a dog which, eight days before, had been inoculated with the bacillus of tetanus from a culture in bouillon. The first tetanic symptoms exhibited by the animal were noted on the fourth day after the inoculation and consisted in opisthotonos. At the same time, all the muscles of the dog became tetanic and the animal was, to all appearances, a rigid cadaver.

It has been maintained that dogs enjoy an immunity from tetanus, but Weyl's experiments have proved the contrary.—*Bulletin Médical*, Feb. 12, 1890.

Treatment of Erysipelas.

Dr. Calvelli recommends the following formulæ for the treatment of erysipelas, in the *Bulletin Médical*, Feb. 16, 1890:

I.

℞ Acidi picrici . . . . . ♏ xxv.
Aquæ dest. . . . . f℥ viijss.

Sig. To be painted on the affected parts five to ten times daily.

II.

℞ Mucilag. acaciæ . . . . . f℥ ij
Acidi carbolici . . . . . ♏xxv–xl.

Sig. To be painted on the affected parts twice daily and allowed to dry.

Michigan State Medical Society.

The twenty-fifth annual meeting of the Michigan State Medical Society will be held in Grand Rapids, Mich., June 19 and 20, 1890. This is one of the most active and enterprising medical societies in the United States, and one whose proceedings are always of interest and value.

Three years ago the Society, appreciating the large number of valuable papers presented at the annual meetings, wisely divided its scientific work into three working sections, namely: Practice of Medicine; Surgery and Ophthalmology; Obstetrics and Gynecology; the afternoon of each day being wholly devoted to sectional work. This plan has worked very successfully, as the last volume of Transactions shows.

The President's annual address this year will be by Dr. Geo. E. Frothingham, Detroit, on "The Need of Extensive Organization and Pursuit of a Fixed Policy as a Means of Promoting our Professional Interests."

The address on Practice of Medicine will be by Dr. W. F. Breakey, Ann Arbor, on "The Mutual Relations and Responsibilities of the Physician and the People in the Promotion of Medical Science."

The address on Surgery and Ophthalmology will be by Dr. F. J. Groner, Big Rapids, on "The Causes and the Remedies for Suits of Malpractice."

The address on Obstetrics and Gynecology will be by Dr. J. N. Martin, Ann Arbor, on "The Relations between Constitutional Conditions and Diseases of the Female Genital Organs."

In order to accomplish its purpose more successfully, the Society would urge that its members join local or County Medical Societies already formed, or use their influence towards organizing such societies, so that nuclei of medical societies may be started, our State being at present behind our sister States in the number of its County Medical Societies.

The Society extends to all graduates in regular medicine, who are residents and practitioners in Michigan, a cordial invitation to attend its sessions, urging upon them the importance of joining the State Medical Society this year.

The Secretaries of the different sections earnestly desire that the members who intend to present papers at the next meeting, will inform them of the fact and send to them their titles and the points to be discussed not later than June 1.

Inquiries in regard to the meeting will be answered by the Secretary, Dr. George Duffield, Detroit, Mich.

Western Pennsylvania Medical College.

The Fourth Annual Commencement Exercises of the Western Pennsylvania Medical College were held in Pittsburgh, Pa., March 27. The degree of M. D. was conferred on twenty-nine graduates, being about twenty-five per cent. of the class in attendance during the past term.

In the evening of the same day, the Alumni Association of the College, now numbering one hundred and twenty members, was entertained at a banquet by the Faculty.

Seaside Home for Women.

The managers of the Seaside House for Invalid Women invite attention to the advantages offered by the Mercer Memorial House, Atlantic City, to sick or over-worked women, who need, and yet can ill-afford, a sojourn at the seashore. The charge for a private room, with nursing, medicines, and medical attendance, is four dollars per week —about one-half its actual cost. Circulars can be obtained by writing to the institution. No one is admitted without previous application.

NEWS.

—Dr. W. R. Hoch has removed to 1502 Walnut Street, Philadelphia.

—There was recently a case of trichinosis in the Ward's Island Hospital, New York. The patient was an Italian.

—The corner-stone of the George L. Harrison Memorial House for Incurables of the Episcopal Hospital, was laid Friday, April 11.

—The ninth annual commencement of the Medico-Chirurgical College was held April 10. Twenty-five graduates received the degree of Doctor of Medicine.

—General Hamilton, of the Marine Hospital service, has been directed by Secretary Windom to make the necessary preparations for attending to the wants of sick emigrants who are at the port of New York after April 18, who may be entitled to Government care.

—Dr. Henry L. Schell, for so many years connected with the Wills Eye Hospital, Philadelphia, died March 15, in San Diego, Cal. His body was embalmed and brought to Philadelphia, where it was incinerated at the Germantown Crematory, in accordance with the desire of the deceased.

—A number of the professors in the St. Louis College of Physicians and Surgeons have resigned. The reason given for this action is that they do not consider it proper to hold their positions practically subject to the will of Dr. Louis Bauer, who is Professor of Surgery, Dean of the College and a member of the Board of Trustees.

—Dr. Edward Chester, who is now spending a few months in this city, after thirty years' work as a medical missionary in Southern India, says that there is an excellent opening for a few good American dentists in Madras. Madras has a population of 300,000 and has no good dentist, so that many persons are compelled to go to Bombay, nearly 1,000 miles away, to have their teeth looked after.

—Spotted fever is reported to have broken out in Union County, Kentucky. A number of children have been attacked, and in each case fatally. The disease is identical in all its symptoms with that which last summer carried off 250 victims in Webster, an adjoining county. In that epidemic neither sex nor age were spared. Only children have so far been attacked this year. The disease is said to run its course inside of 36 hours. Its approach is heralded by intense pain at the base of the brain. A burning fever speedily follows. The tongue becomes swollen and hard, unconsciousness ensues and death follows. After death the body becomes spotted with yellow blotches, the limbs swell and the whole body turns black. The schools have been closed and the people are leaving.

OBITUARY.

DR. HENRY HOLLINGSWORTH SMITH.

Dr. Henry Hollingsworth Smith, the eminent and well-known surgeon, died at his residence in Philadelphia, April 10, after an illness of ten days, in the seventy-fifth year of his life. Dr. Smith was born in Philadelphia, December 10, 1815. He was graduated from the College Department of the University of Pennsylvania in 1834, and was graduated from the Medical Department of the University in 1837. He was Resident Surgeon of the Pennsylvania Hospital for two years, and then spent some time in various European hospitals. He became Surgeon to St. Joseph's Hospital in 1849, Surgeon in the Episcopal Hospital soon afterwards, and one of the surgical staff of Blockley Hospital in 1854. In 1855 he was appointed Professor of Surgery in the Medical Department of the University of Pennsylvania, and resigned to become Professor Emeritus in 1871.

At the beginning of the civil war he was appointed to organize the Hospital Department of Pennsylvania, and at the same time made Surgeon-General of Pennsylvania. In this capacity he contributed much to the efficiency of the medical service of the Pennsylvania Reserves and other State regiments. After thoroughly organizing the department of which he was in charge, he resigned his commission in 1862, and has since been actively engaged in the practice of his profession. He won the warmest thanks of uncounted relatives by inaugurating the system of embalming the dead on the battle-ground. No act in the medical and hospital department of the army won more praise than was at that time and has since been awarded this.

Dr. Smith was widely known as a medical author and teacher, and he took an active interest in the questions of medical politics which have engaged the attention of the profession in this city and throughout the country during the past few years.

BURN BRAE

A PRIVATE HOSPITAL

--FOR--

MENTAL and NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

EXTENSIVE AND BEAUTIFUL GROUNDS, affording perfect privacy and pleasing variety. House and surroundings unusually attractive and cheerful. Heat, light and ventilation perfect.

A PLEASANT, SAFE AND HEALTHFUL HOME,

With constant professional supervision. Music, games, open-air amusements, boating, etc., are provided for patients.

THE OLDEST INSTITUTION OF THE KIND IN THE UNITED STATES.

Both sexes received. A limited number of opium habitues admitted. Pleasant companions for female patients.

LOCATED A FEW MILES WEST OF PHILADELPHIA,

At Primos Station, on the Philadelphia and Media Railroad, from Broad Street Station, Philadelphia, Pa.

CHRONIC EMPHYSEMA. — EMPHYSEMA WITH ACUTE BRONCHITIS.[1]

BY JAMES TYSON, M. D.,

PROFESSOR OF CLINICAL MEDICINE, UNIVERSITY OF PENNSYLVANIA.

Chronic Emphysema.

Gentlemen: This patient is sixty-six years old, and presents a negative family history. His employment has, however, some bearing on his disease. He is a machinist, and forced to work a great part of his time exposed to the irritation of minute particles of iron pervading the air he breathes. He has lived, too, in a raw and cold climate, but he has always had good food and has been well clothed. He has had gonorrhœa and syphilis, and also malarial and typhoid fever. His present illness dates twenty years back. For a long time he had a cough which was worse in winter, and this is still the case; he loses wind upon slight exertion, and is subject to attacks of dyspnœa which nearly always occur at night. It is plain that this history suggests physical examination of the patient's chest. Inspection shows a change in the shape of his thorax. You will mark that it goes down abruptly on each side, and has not the curves that we naturally find in health. It is cylindrical in shape; and this term expresses the condition better than the customary word barrel-shaped which, however, is the expression generally used to describe such a chest. You will also mark a deep depression over the sternum, and the same state of affairs over both clavicles. His rate of breathing is from twenty-four to thirty as contrasted with the normal, eighteen to twenty, respirations per minute.

By percussion we find in health that the liver dulness generally begins in the mam-

[1] Delivered at the Philadelphia Hospital.

mary line at the sixth interspace. Here, as we percuss downwards, we find that in nearly the whole area in which we ought to meet with hepatic dulness there is a resonance. This resonance extends to the eighth and even to the ninth rib before absolute dulness is arrived at. Below this the sound is dulled for the distance of a couple of fingers' breadth, and then we come to the tympany of the abdominal region. We see then that the liver is displaced downwards. Now on the left side we find this extreme resonance extending, not merely to the fourth, but to the seventh rib. The apex beat of the heart is in its normal position, but very weak and difficult to locate. On both sides of the chest the interspaces are abnormally deep. The reason for this is that, as the chest wall expands, the lungs do not follow them, so that there is in the pleural cavity a vacuum which causes these intercostal spaces to recede. The result then of our examination by percussion is that we find over both lungs a hyper-resonance which, moreover, obscures or takes the place of the dulness in the regions of the heart and liver. On the left side the dulness of the spleen is entirely concealed by the hyper-resonant lung. Behind, the chest is shaped like a cylinder and not so much like a double truncated cone, as in health. Over the regions of both scapulæ the resonance is, as usual, somewhat lessened. Below them we again find this hyper-resonance extending quite down to the bottom of the chest.

On auscultation I hear a prolonged vesicular murmur, not louder but rather lower than normal. The inspiration is shortened and less loud than in health, but the expiration is prolonged, and this is more noticeable anteriorly than posteriorly. Expiration on the right side is very markedly prolonged; and on the left side, although this condition is not so striking, it is still sufficient to be noticed at once. The heart sounds are normal, but distant and difficult to hear.

The history of the case, extending over such a long period; the fact that he did not begin to lose flesh to any great degree until the last six or seven years, together with our finding everywhere hyper-resonance instead of dulness—all point to this being a case not of consumption, as one might think from hastily looking at the man's appearance, but of chronic emphysema. Now, in this disease, we have a permanent dilatation of the air vesicles, associated with the loss of their elasticity. This condition is often compared to that of an India rubber balloon that has been overstretched until it has lost the power of contracting to its former size. Moreover, the partitions between the different air vesicles become destroyed, so that three or four of them unite together, especially at the edges of the lungs and then the organ or, at least, the part of it most affected, resembles somewhat the frog's lung.

The emphysema may be either partial or general. If it extended over the whole of both lungs, of course, the patient could not live. But I have seen *post-mortem* lungs so thoroughly emphysematous that it was surprising that their owners lived as long as they did. When these vesicles become destroyed and several merge into one, the lung becomes hyper-resonant; and as the minute ramifications of the blood-vessels about these destroyed vesicles become, in course of time, themselves destroyed, the effort of the heart to drive the blood through the diminished vascular space becomes greater and greater until hypertrophy of the right ventricle results.

Emphysema is not a primary disease, but is a secondary result of chronic bronchitis, as is well shown in this case. It is brought about by either inspiratory or expiratory strain. When a person coughs hard he inspires deeply and much air is introducded into the lungs, and the vesicles are dilated by its entrance. Especially when it is turned aside from its usual path by obstructed areas; but expiration has probably more to do with causing emphysema than inspiration; when mucus plugs up certain of the air tubes, and the vesicles to which they lead cannot empty themselves, the latter are compressed by the chest walls and yield in the directions of least resistance and become over-distended, and lose their power to contract. These situations are the apices and edges of the lungs; and these become emphysematous sooner than the central parts. The results of this disease are, on the whole, well explained by physical laws.

As to *treatment*, it is impossible to restore the lost partition between the minute air vesicles or to reduce them to their natural size. Our great aim should be to get the afflicted person to accommodate his manner of living to his diminished air space. The emphysema is not only dependent upon the accompanying bronchitis, but is greatly aggravated by it, and as this latter affection be-

comes better or worse so is the former trouble lessened or increased. Therefore, we must treat the accompanying bronchitis. When the disease is chronic and expectoration profuse, the stimulant expectorants are indicated, of which there are none better than the carbonate of ammonium. Senega is included in the same category. These should be exhibited in doses of from five to ten drops of the latter and five to ten grains of the former. Counter irritation in the form either of tincture of iodine or a weak mustard plaster—say one part of mustard to four parts of flour or Indian meal—so that it may remain on for a good while, is also of value. As an alterative during the chronic condition, we may resort to the use of the iodide of potassium, while the tincture of belladonna is useful in relaxing spasm; for during the acute exacerbations or the attacks of asthma the symptom of dyspnœa is so serious and painful, that we have to resort at once to some special treatment to relieve it. Now the cause of this shortness of breath is an imperfect aëration of the blood, because the air in the lungs is not kept sufficiently renewed. What is wanted is a more satisfactory interchange between the external atmosphere and the air in the lungs and whatever will contribute to this end is beneficial. Therefore it is well for the patient to accustom himself to the habit of alternately compressing and relaxing his chest walls with his hands, or, what is better, have this alternate compression and relaxation practiced upon himself by another person, so that his lungs may become thereby more perfectly emptied of their worn-out air. This same object is accomplished by breathing into rarefied air or by breathing condensed air. In the former case the air-chamber into which the patient breathes, being under less pressure than the air in his lungs, there is a comparative vacuum outside, so that by this means the air in the remote parts of the lung is drawn out and then, of course, its place in the lung filled out by fresh air from the outside. The same effect is gained, though in a different way, by one's breathing into condensed air. Here, the air being under greater pressure than that in the patient's lung, forces itself into the different parts of that viscus, into the remote air cells and thus brings about the interchange between the internal and external air. This plan is not as good as the breathing into rarefied air. For these acute attacks of asthma, which so frequently accompany the emphysema, the best medicinal treatment is either by nitrate of amyl, chloroform, belladona or the iodide of potassium. Pearls of the nitrite of amyl may be carried by the patient about with him and one of them may be broken and its contents inhaled when needed. If the chloroform is inhaled, it would be necessary for it to be administered by another person. The tincture of belladonna may be given in small doses, often repeated. Iodide of potassium would have to be administered for a long time to do any good. A very useful remedy is strychnine as an expiratory stimulant. It should be given in full doses, certainly as much as $\frac{1}{20}$ grain and even $\frac{1}{16}$, reached by gradual increase from smaller doses.

Emphysema with Acute Bronchitis.

This next patient is much younger than the one who preceded him. His occupation has been that of a laborer. Here, too, the family history is negative. His health was good in childhood. He, too, worked in dust; has been pretty freely addicted to the use of alcohol and has had specific disease. He had an attack of pneumonia in 1884 and this probably has some connection with his present complaint. He has had a cough, worse at times, and attacks of dyspnœa for the last four years. He also had bronchitis, which was worse in the fall and winter seasons and, moreover, attacks of asthma which nearly always occurred at night; so that he has, on the whole, a good many symptoms similar to the other case.

Upon examining him by inspection we find that he, too, presents the condition characteristic of constant expiratory strain. Here, too, we see the cylindrical or barrel-shaped chest, which is straight up and down, with deep depressions between the ribs and about the clavicle where the muscles are attached. He presents the superior thoracic type of breathing—that of woman. Percussion on the right side shows resonance down below the seventh rib, because the liver is displaced downwards by the lung. The heart's dulness is obscured by the overlying lung and that of the spleen is hardly perceptible. By auscultation we find that the inspiratory murmur here is louder than in the former case. The characteristic peculiarity of emphysema, that the duration of expiration is increased while that of inspiration is decreased, is here very marked. We hear also "cooing" râles, which are

symptoms of bronchitis. This is what we might expect, as the man did not come into the hospital until yesterday. In addition to the cylindrical-shaped chest, upon examining this man behind, we find that he has the drawing together of the scapulæ and that consequent deepening of the vertebral gutter. These phenomena are also common in emphysema, from the overwork of the muscles in their efforts to make the chest walls accomplish or supplement the imperfectly performed functions of the lungs. Moreover, this is a local disease and in this case it is more marked on the left than on the right side, that is, the resonance and other signs of emphysema on the left are more marked than on the other side.

Under the head of treatment may be mentioned in this case the comfort and rest of a hospital. These patients who are poor nearly always improve as soon as they come here, independent of the medicines they receive; because they get good food, rest and protection from the weather. As this man was only admitted yesterday, the symptoms of his disease are rather those of acute bronchitis. We do not hear the moist bubbling, as in the previous case, but sonorous and sybilant râles. Therefore, we do not need the stimulant, but relaxing expectorants, such as tartar emetic or ipecac. He might now take a prescription like one of the following:

℞ Syrup of Ipecac . . . . . f℥ss.
Sweet Spirits of Nitre . . . . . f℥vj.
Simple Syrup, or Sprup of Wild Cherry . f℥ss.
Neutral Mixture, enough to make . . . f℥vi.
Sig. Take one tablespoonful every three hours.

Later we may add to this prescription two drachms of the muriate of ammonium or still later, carbonate of ammonium, omitting the ipecac altogether. Locally he should have upon his chest a large, warm mustard poultice, composed of one part mustard and four parts corn meal, which may be left on for some time.

—The special board of engineers appointed by the Secretary of War to examine and report upon the most available point on the Gulf coast west of the Mississippi for a deep-water harbor have selected Galveston. Their report is now before Congress. The expense of improving Galveston harbor so as to fulfil the requirements is estimated at $6,200,000.

EMPHYSEMA.—EMPHYSEMA WITH BRIGHT'S DISEASE. — EMPHYSEMA COMPLICATED WITH PHTHISIS.

BY J. M. ANDERS, M. D.,
PHILADELPHIA.

Emphysema.

Gentlemen: The history of the first man whom I show you to-day is as follows: He is fifty-nine years old; his family history reveals that his father died of phthisis at an old age, his mother living to an old age also and having had emphysema and asthma. When a boy he had typhoid fever, and at twenty he had what was thought to be brain fever. After that he was well until twenty years ago when he had an attack of articular rheumatism. Four years ago he began to suffer from asthmatic attacks, terminating with profuse expectoration. From these symptoms one would expect the presence of emphysema and it is with this idea foremost in my mind that I begin to examine his chest.

Inspection shows that the thoracic portion of the spinal column is more curved than normal. There is bulging behind and in front—a prominence giving to his chest the characteristic barrel-shape. His inspiration is quick and short; his expiration, prolonged and labored. When he breathes, the whole chest is moved slightly upward and downward as one solid casing. The normal elasticity of the lungs is not sufficient, hence they do not empty themselves at each breath. Thus there is a great amount of the residual air left behind them at each respiration. The intercostal spaces protrude behind. The heart is overlapped by the lungs. The apex beat is much displaced towards the right side and also in a downward direction. For these reasons the area of cardiac dulness is very small.

Percussion reveals hyper-resonance over his entire chest. The percussion note in emphysema is never purely tympanitic, but partly of a vesicular quality. The lung has pushed down the diaphragm and the breathing is, to a great extent, abdominal. Some physicians go so far as to divide all cases into those characterized by abdominal

[1] Delivered at the Philadelphia Hospital.

respiration and those in which the respiratory movements are more marked above.

Auscultation shows a prolonged wheezing expiration, and when you have associated the three signs: weakened vesicular murmur, prolonged expiration, and hyper-resonance on percussion, you may be certain of the existence of emphysema. Pneumothorax gives rise to a hyper-resonance at first; but here auscultation reveals exaggerated respiratory sounds. In pleurisy there is flatness on percussion when effusion takes place. In phthisis we get dulness on percussion, generally in one of the upper lobes, together with harsh vesicular murmur, and more or less bronchial breathing. In capillary bronchitis you have greatly hurried breathing, a rise of temperature, a bad cough, and the expectoration of considerable sputum. Pleurisy generally affects both lungs and in this respect resembles emphysema, which also usually affects both organs in the course of time.

During the progress of emphysema the patient is often comparatively comfortable in summer, but in winter the cough and asthma set in again. The associated bronchitis often bears a causal relation to this disease, especially when the emphysema is local. When the bronchitis comes late in the disease it is due to a passive congestion. In this man's case the bronchitis preceded, and was the cause of the emphysema. Therefore, it is worse in winter.

If emphysema is due to some sudden great effort, or is brought on in children by the whooping-cough, it is often curable. Jenner thinks that this disease is due to a fibroid degeneration of lung tissue, while Williams attributes its causation to fatty degeneration. The indications for treatment are to arrest the degeneration by iron and arsenic and to restore the power of the over-distended lung. This latter object is best accomplished by breathing condensed air, at the same time expiring into rarefied air. Then you should always treat the associated bronchitis. The asthma, too, may require special treatment. Each hospital has its formula for cigarettes, which give temporary relief.

Again, the tincture of lobelia is given in twenty-drop doses every half hour until the symptoms are relieved. In order to break up the tendency to recurring attacks of asthma, the iodide of potassium in ten-grain doses, three times a day, is recommended.

Emphysema with Bright's Disease.

This man is seventy years old, and he comes from a long-lived family. His father died, at the age of eighty-four, of articular rheumatism and his mother of old age. He had eleven brothers and two sisters and his own family number ten children, all of whom, except one, are still living. He had rheumatism last year, and in May, 1889, he was seized with dyspnœa and fever, together with a fearful headache. He went to the Episcopal Hospital, where he was treated for bronchitis and asthma. He left there at the end of three weeks slightly improved. He has had one attack of asthma while here and for this he received a hypodermic injection of morphine.

Examination by inspection shows that the chest is enlarged, but not barrel-shaped. The apex beat of the heart is seen in the epigastrium. Percussion, too, confirms the testimony of inspection that the heart is displaced downward, and that the area of its dulness is decreased. There is increased resonance of the lungs. Auscultation reveals a weakened vesicular murmur and the expiration is prolonged. The main physical signs are: weak vesicular murmur, prolonged expiration and semi-tympanitic resonance; and they point to emphysema. When he was admitted he was treated for chronic bronchitis. The emphysematous condition persisted and the attacks of asthma at night grew worse. About three weeks ago his urine showed some albumin and some epithelial and granular casts. Some authorities say that all cases of emphysema, that terminate fatally, exhibit albumin and casts in the urine. While I am prepared to admit that it does occur at times, I think it is going too far to claim that it occurs in all, or anything like all, fatal cases. When Bright's disease does occur it is in the majority of instances the large, white kidney, whilst it sometimes takes the form of chronic congestion. Many of these cases of kidney disease seem to develop suddenly. In nephritic complications you will have the worst forms of nocturnal asthma. As this man's urine indicates Bright's disease and he is already anemic, he will be given one tablespoonful of Basham's mixture three times a day.

Emphysema complicated with Phthisis.

This old man's occupation is that of a laborer. His family history is good. At

fifteen he had pleurisy; twelve years ago he had typhoid-pneumonia, and later, cough, profuse expectoration and night-sweats. He recovered from this, but later began to cough again. He was admitted here a good while ago and showed then serious lesion at the apex of the left lung. Here the emphysema is only partial or compensatory. There are some who say that you cannot have emphysema and phthisis in the same subject, that in emphysema you have an anemic condition of the lungs, while the great requisite in phthisis is hyperemia. But in this case we had, first, a tuberculous process, and later a compensatory emphysema. The antero-posterior diameter of the right chest is enlarged, and we have a distinct impulse of the heart's beat beyond the nipple line. In emphysema the right side of the heart is frequently dilated from general capillary stenosis of the lungs.

On ausculting the right side of the chest I get a weak vesicular murmur and prolonged expiration; and on percussing, hyper-resonance. On the left side I hear subcrepitant râles everywhere, distant bronchial breathing and the percussion resonance is diminished. Therefore, the whole of the right lung has undergone hypertrophic emphysema while the left lung has been becoming tuberculous. In cases like this the prognosis is grave and the treatment should be, to a great extent, directed to the general condition.

COMMUNICATIONS.

TROPHO-NEUROSIS AS A FACTOR IN THE PHENOMENA OF SYPHILIS.[1]

BY G. FRANK LYDSTON, M. D.,
CHICAGO, ILL.

[CONCLUDED.]

Even in congenital syphilis we can see evidences of tropho-neurotic disturbance. The peculiar affinity of the syphilitic process for the epiphyso-diaphysial junction of the long bones is strikingly suggestive. It is here that the processes of growth and nutrition are most active, and tissue building most rapid. It is, consequently, at this point that disturbance of the trophic function of the sympathetic which presides over the physiological processes of nutrition and growth would be most likely to be manifested by pathological changes. A perversion of the function of the sympathetic would result in imperfect differentiation of the cells of the part; and, as the rapidity of proliferation of cells is in inverse proportion to their degree of differentiation, a heaping up of the young material is to be expected. Associated with this imperfect differentiation of cells, we have a tendency to degeneration; for it may be formulated that the tendency to degeneration is also in inverse ratio to the degree of differentiation. This imperfect differentiation, with a consequent tendency to degeneration of young germinal material, is the characteristic feature of all the lesions of syphilis, no matter at what stage of the disease they may develop.

The physiological effects of the remedies upon which we depend for the cure of syphilis are evidences of the neurotic character of syphilitic phenomena. It is shown that mercury and iodide of potassium, although very efficacious in syphilis, are in no sense directly curative, their beneficial effects being dependent upon their power of inducing fatty degeneration and elimination of the products of the syphilitic process rather than upon any special controlling or antidotal effect upon the poison *per se*, whether this poison be a virus, germ or cell. In reviewing the opinions of our best syphilographers regarding the treatment and prognosis of syphilis, one is impressed with the idea that syphilis is a disease which runs a natural course in spite of treatment, the physician being incapable of doing more with his remedies than to remove the effects of the disease as fast as they appear, thus preventing as far as possible permanent damage to the affected tissues. As far as aborting the natural course of the disease is concerned, he is absolutely helpless; and apparently his success in the treatment of the disease is inversely to the vigor of his attempts to antidote or stamp it out.

If the neurotic theory of the essential condition in syphilis be correct, in our efforts to discover a specific remedy for syphilis we have been necessarily led away from those lines of research which would lead to a correction of the principal element in the production of the syphilitic phenomena. The severity of the results of syphilis would appear to depend (1) upon the individual susceptibility of the nervous system of the patient; (2) upon his constitutional

[1] Read at the meeting of the Southern Surgical and Gynecological Association.

condition, and, incidentally, on the resisting power of his tissues; (3) upon the action of remedies, this being by no means the most important consideration.

The involvement of the fauces and pharynx characteristic of secondary syphilis, has been explained upon the ground of lymphatic engorgement, the primary cause of which is the abundance and superficial character of the lymphatic capillaries of the affected parts. It is a noteworthy fact, however, that there is but little swelling, pain and tenderness accompanying the syphilitic sore throat, provided ulcers be absent. There is also little or no tendency to ulceration in the majority of cases in the early part of the disease. There is comparatively little heaping up of syphilitic material. These characters would lead one to suppose that there is something behind the localized proliferation of cells—if such exist; something, too, which will explain the appearance of morbid phenomena at this particular point, aside from mere anatomical peculiarities. For obvious reasons it has not been clearly shown whether the same efflorescence and engorgement does not occur in the other portions of the alimentary canal in the early period of syphilis. Admitting that there is a diffuse accumulation of cells in the pharyngo-faucial tissues, there should be something more than local anatomical peculiarities to explain it. Is it not a result of vaso-motor changes similar to those which prevail in the roseola, and which are due to the impression of the syphilitic poison upon the central nervous system? The same condition, in all probability, prevails in other portions of the alimentary tract, which, as is well known, are intimately associated with the sympathetic nervous system. It is only at this point, however, that the parts affected are so superficial as to be open to observation. At this point, moreover, causes of irritation are more prevalent than in other portions of the alimentary tract. The food which is swallowed, rapid changes of temperature incidental to the function of respiration or to the ingestion of fluids at various temperatures, the use of the voice, the contact of irritating secretions from the nose, and the inhalation of irritating substances from the atmosphere, might quite rationally be expected to contribute to the tendency to localization of the syphilitic process in the throat. In the presence of such local causes of irritation, vaso-motor disturbance incidental to the impression of the syphilitic poison upon the central nervous system might be determined at this point, while absent in every other situation.

As we have seen, the vaso-motor impression which underlies the development of the roseola is substituted later on for a more or less pronounced trophic disturbance, as manifested by the heaping up of neoplastic material, the development of pus, the occurrence of ulcerations, etc. *Pari passu* with the supervention of this trophic disturbance in the case of the skin we have a similar state of affairs in the pharynx and mucous membrane of the mouth, as manifested by the development of mucous patches, ulcers and macular eruptions, the latter being particularly marked upon the roof of the mouth.

On careful observation of successive crops of lesions in syphilis, it will be found that the tendency to destruction of tissue and to the involvement of various important functions of the body grows more pronounced as the case progresses. We see, therefore, in watching a case from its inception, the gradual supervention of a trophic upon a vaso-motor disturbance, and as the case progresses this trophic aberration becomes more and more pronounced, until finally in the period of the so-called sequelæ we have marked destruction of tissue in various situations—a destruction so marked as to have led to the impression at one time that the syphilitic poison produced in such instances corrosion of the tissues. In the absence of a corrosive power of the syphilitic poison—and as we know its infectious properties decrease as the case progresses—the only logical explanation of the serious effects of late syphilis is the theory of thropho-neurotic disturbance.

Let us glance at the series of morbid phenomena in a typical case, and the truth of the foregoing assertion is at once apparent.

First, we have a macular eruption or perhaps an efflorescence of the skin, which is not at all raised above the surface. This—the roseola—does not produce any destruction of tissue. Later on we have the development of papules; a little later in the natural order of succession, pustules, perhaps followed by ulceration. Still later we have marked ulceration of an ecthymatous or perhaps rupial character. Interspersed with these various later lesions or occurring alone, we may have a development of scaly lesions, —sometimes tubercular syphilides. Coincidentally with the papules we have the ap-

pearance of sore throat, followed later on by mucous patches and perhaps ulceration. As the case progresses, the bones may be affected; iritis may occur; well along in the period of sequelæ, necrosis of the bones may develop. It will be found that the tendency to suppurative processes and to destruction of tissue increases as the intensity of the infection diminishes. The later lesions are found to be frequently associated with disturbance of a known nervous character, cerebral syphilis in its various forms being quite apt to occur.

The exceptions to the gradual increment of severity of syphilitic lesions are so unusual that they are now designated as precocious. Malignant or precocious cases of syphilis are explicable in my opinion only upon the theory of idiosyncrasy.

It is in the late secondary and sequelar lesions of the disease that the apparent tropho-neurotic character of the manifestations is most pronounced. I had long been impressed with the peculiar course of some of the lesions of bone in late syphilis, particularly those affecting the head and face. It had seemed to me that the destructive effects exerted by the morbid process upon the bony tissue was greatly disproportionate to the objective and subjective phenomena which preceded the actual destruction. For example, I think that, upon reflection, it will be found that the objective morbid phenomena which precede the necrosis *en masse* of various portions of the palate and of the superior maxillary and nasal bones are comparatively slight when we take into consideration the fact that the affected bone is entirely destroyed. Indeed, it often seems that the first objective phenomena perceptible in cases of necrosis of the parts mentioned is incidental, not to the destruction of the bone, but to an attempt on the part of nature to rid the tissues of offending foreign material. Thus I have observed cases in which the greater portion of the palate was entirely destroyed, yet very little manifestation of trouble was apparent until suppuration occurred with a small point of ulceration of the soft parts covering the bone and the discharge of a small quantity of pus—a quantity, by the way, so small as to be entirely disproportionate to the extent of the morbid process. On passing a probe into the small sinus thus formed, one who is not thoroughly conversant with the peculiarities of such conditions would probably be surprised to find that a large portion of the bone is dead and perhaps loose in the tissues. It will be found upon observation of processes other than syphilitic, which produce necrosis or caries of bone, that there exists prior to the death of the bone structure, quite pronounced objective phenomena in the way of pain, swelling and deformity of the part, these symptoms indicating the existence of proliferated inflammatory material which subsequently produces destruction of the vitality of the bone by simple pressure. Those morbid phenomena in syphilis, which involve bone or periosteum in the early part of the course of the disease, are accompanied by objective phenomena relatively more prominent than those late lesions which are now under consideration; yet, at the same time, they are rarely followed by caries or necrosis. These processes, it seems, are reserved for the late secondary or sequelar period of the disease. Thus it will be seen that, although the local process is apparently more severe in the early cases, destruction of the vitality of the bone is not so likely to occur. There is a marked difference between the nodes and diffuse sub-periosteal swellings of early syphilis and the condition of the bone and periosteum which precedes necrosis *en masse*, or, for that matter, caries, in the late stages of the disease. In addition to the disproportion between the degree of destruction of bone and the objective phenomena preceding such destruction, another point worthy of comment is the fact that syphilis possesses the power of dissecting out definite portions of bone tissue, apparently by cutting off their nutritive supply—in a manner as clean as could be effected by the knife. Thus I have specimens in my possession of the intermaxillary bone, portions of the alveolar process of the maxilla, the palatal and nasal processes of the superior maxilla, the malar bones and the nasal bones, which became necrosed and loosened, and were removed from cases of late syphilis. These fragments of bone present as natural a conformation in many instances as in their healthy condition.

As far as I have been able to observe, there seems to be a special predilection in cases of late syphilis for those parts supplied by the fifth nerve, indicating that the portion of the sympathetic system which presides over these parts is especially sensitive to the syphilitic impression.

I have found in some instances the tendency to unilateral destruction of bone

tissue particularly marked. Thus the palatal process of the superior maxilla upon one side, or the superior alveolus upon the other, may necrose and give way without the corresponding portion of bone becoming affected. Indeed, it seems that in most instances in which necrosis attacks the bones of the face, it is impossible to check the process until the line of demarkation represented by the anatomical outline of the affected bone has been reached. The peculiar manner in which one-half of a structure may be dissected away by the sequelar lesions of syphilis, is exemplified by a case of syphiloma of the tongue which recently came under my observation, in which the sloughing of the organ was limited by the raphe. This case subsequently went on to malignant transformation. I removed the tongue with the galvano-cautery; the disease recurred; and the patient died of hemorrhage several months later.[1]

I have had several cases recently in which that portion of the superior maxilla corresponding to the intermaxillary bone was dissected out by the syphilitic process, with resultant loss of the incisor teeth, the remainder of the jaw remaining intact. There appears to be a peculiar predilection of late syphilis for this portion of the jaw. I have several cases in which caries occurred in this situation, with a consequent loss of one or more perfectly healthy teeth. These cases have appeared to me to be so characteristic that I have come to regard loss of the incisor teeth, without any apparent cause, as almost positive evidence of syphilis.

An interesting case, illustrating the unilateral limitation of some late lesions of syphilis came under my observation recently. The patient was a gentleman who had an obscure history of syphilis, dating some years back. Several weeks before coming under my observation, ulceration began at the roots of the moler teeth upon one side and extended outward to the palate. When I first saw the case the ulceration had extended outwards upon the hard palate for about three-quarters of an inch and forward to the median line, when it abruptly stopped. The appearance of the ulceration was quite typical. There was no disease of the teeth or jaws to account for it. Healing was quite rapid under appropriate anti-syphilitic treatment.

[1] Apparent cancerous transformation of syphiloma of the tongue. Amputation by the galvano-cautery. *Medical Record*, Oct. 26, 1889.

Another interesting case of a somewhat similar character is that of a gentleman who had syphilis seven or eight years ago. For the last three or four years he has had occasional symptoms of the disease. A few months ago ulceration occurred about the roots of the upper incisor teeth, and was attended with slight caries of the intermaxillary bone. The process was checked by appropriate treatment; the teeth, which were loosened, finally becoming perfectly solid. About six or eight weeks after the ulceration was healed the patient consulted me for supra-orbital and infra-orbital neuralgia and hemicrania. This resisted all treatment, except anti-syphilitic remedies. It yielded readily to iodide of potassium in large doses. Within a few days the patient has again consulted me for paræsthesia of the right side of the face, which he noticed for the first time while being shaved. His face having been excessively tender before, he very speedily noticed a lack of sensibility under the razor. Associated with this paræsthesia, there is obscure pain, which he locates back of the eyeball. The *ensemble* of symptoms in this case points to central disturbance, and shows a manifest predilection of the sequelar lesion for the fifth cranial nerve.

The association of obstinate tubercular syphilides with nervous syphilis is well known. It seems that the danger of involvement of the central nervous system is directly proportionate to that of severe syphilides.

In considering the tropho-neurotic character of the late lesions of syphilis, I do not ignore the fact that syphilis may act directly upon the nervous system in several different ways:

1. By the direct effect of syphilitic deposit upon the nerve cells or fibres, or membranes of the brain and spinal cord.

2. By changes in the membranous envelopes of the brain and spinal cord.

3. By deposits in and about the blood-vessels which induce circulatory disturbance.

4. By a proliferation and condensation of connective tissues which remains after the syphilitic material *per se* has been removed.

There is probably a difference in the late and early forms of syphilitic lesions, in the manner in which the tropho-neurotic element is brought about. Thus it may be due, in the first place, to a direct impression of

the syphilitic poison upon the sympathetic nervous system; secondly, upon direct pressure upon the nervous structures; thirdly, upon a disturbance of function and nutrition of the nervous structures incidental to interference with blood supply.

It is probable that mercury acts upon the nervous system in very much the same manner as does syphilis. It is very difficult to differentiate late syphilitic lesions of the bones and of the mucous membranes from those directly due to the action of mercury. That mercury exerts a powerful effect upon the sympathetic nervous system is, it seems to me, shown conclusively by the phenomena of ptyalism, which cannot be accounted for solely upon the theory of the production of irritation. The well-known power of mercury over the secretions is probably due to its influence upon the sympathetic ganglia. When the injurious action of mercury is superadded to syphilis, there is a more marked tendency to tropho-neurotic phenomena than in well-treated cases of the disease. Indeed, the excessive use of mercury often seems to determine the predilection of late syphilis for the bones of the head and face. It is quite as capable of producing necrosis or destructive ulceration of these parts, as is syphilis *per se*.

Positive demonstration of the dependence upon nervous disturbance of the phenomena which I have outlined is, of course, difficult; but the inferences which I have drawn appear to me to be logical. In considering the question of trophic disturbances, in their relation to destructive syphilitic processes, it is well to remember the familiar physiological experiment of section of the sympathetic in the neck of the rabbit. The same experiment is also interesting as bearing upon the faucial congestion of early syphilis. The reddening of the ear of the rabbit, the inflammation and sloughing of the cornea incidental to section of the sympathetic are certainly suggestive. To carry the analogy of this physiological demonstration a little further, I would call attention to the serious corneal trouble which sometimes results from herpes frontalis *seu* orbicularis.

DEXTRINE MUCILAGE. — Four hundred parts of dextrine are stirred into 400 parts of water; then add 200 parts more of water, 20 parts of glucose and 10 parts of aluminum sulphate; heat the mixture to 195° F., when it will become thin and transparent.

INFLUENZA—LA GRIPPE.[1]

BY WILLIAM B. DEWEES, A. M., M. D.,
SALINA, KANSAS.

Mr. President and Fellow-Members: The repeated accounts given during the pandemic prevalence of the late epidemic of influenza, in the columns of both the medical and the daily press, and a personal experience with the disease, has familiarized the profession so extensively with all the divers phases of this most unpleasant malady, that anything said on the subject may seem trite. Nevertheless, the occasion is one which cannot be allowed to pass with no formal notice and full consideration by this Society.

In presenting this subject for discussion, the time allotted allows scarce more than bringing out the more salient features, and even in this I find myself somewhat at a disadvantage. The absence of reliable statistics regarding the prevalence and progress of this wide-spread disease, makes its exact study more difficult. From the knowledge we have, influenza is not in itself a grave disease; yet its complications and the sequences are sometimes most important. This fact alone not only justifies, but demands a close examination of the clinical history of this disease—more especially as manifested during the last epidemic.

Influenza is by no means a new disease, though most of the medical men who have been graduated within the last ten years have seen nothing of it prior to the last epidemic. The earliest record known of this disease is probably found in an outbreak in the Athenian army in Sicily, 415 B. C., as recorded by Diodorus Siculus. From the ninth and tenth centuries of the Christian era, references to epidemic influenza—now called epidemic catarrhal fever or *la grippe*, etc.—begin and multiply; and from that time to the present, the literature of the subject has grown steadily. History shows that since the year 1173 to the present time, there have been sixty-two epidemics of influenza in Europe, America and elsewhere, averaging one in about every eleven years. During this period it assumed a pandemic form fifteen times. One of the most remarkable epidemics of which we have record is that which started in China in 1830, and swept rapidly over Asia, Europe and America,

[1] Read before the Golden Belt District Medical Society of Kansas, April 3, 1890.

lingering here and there, and breaking out afresh in places until 1833.

Since that time there have been a number of less wide-spread epidemics, including that which occurred in this country in 1879—in which I had my first experience with the disease. It may not be out of place to note in this connection—as most of you can recall with me—the facts of a similar disease being very extensively prevalent among horses at the same time, which was chiefly known as "pink-eye," and proved much more fatal than the disease in man. The disease has always been particularly remarkable in this, that it has been the most widely and generally-spreading epidemic known. It has seldom appeared in any one country without appearing successively in every other part of it. The last epidemic, which has just swept the world from east to west, has excited universal attention, and sufficient time has at length elapsed, even in this country, to enable us to present our recorded observations and to exchange our individual views in regard to it, founded upon actual observations and not upon mere hypothesis.

According to the journals, the last epidemic made its first appearance in Europe, where the first cases recognized were observed in St. Petersburg, October 15, 1889, its diffusion and spread being so rapid and general that by November 17 it had invaded Asia, Finland, Vienna, Paris, etc., and by December 20 it was epidemic in nearly all the capitals and large cities of Continental Europe. In this country it was first recognized in Boston, December 17, in New York City, December 20, in Chicago, December 23, etc., thus extending from the Atlantic to the Pacific, from Canada to Mexico and Central America within one month. Practically, this epidemic has extended from St. Petersburg to the Pacific Coast, over two continents from north to south, within three months—extending over a greater area and with greater rapidity than any epidemic of which we have a record.

The disease made its advent in Salina, Kansas, about December 25, 1889, gradually but surely making inroads until about ten days later, when it began attaining rapid headway, and prevailed extensively for about eight weeks. Thereafter its subsidence was marked, though less rapid than its onset, and it continues to manifest itself in isolated cases. During this period, it is safe to estimate that one-third of the population of this city was affected by the poisonous influence of the disease, but that, owing to the mildness of the general type of the affection, probably only one-half of the number affected came under the care of the medical profession. While there have been a great many cases and much sickness, no death is directly traceable to the influenza *per se*. The total number under my care and observation during this period has been over five hundred cases, the largest number of cases I have seen sick in bed in one day being forty-one. The period of its greatest prevalence was from January 14, 1889, to February 11, 1890, during which four weeks there came under my care three hundred and ninety-six cases. In describing the disease as observed in these cases, I shall first note the general symptoms in their usual order of appearance. The disease came on like a severe cold, but with much greater and more speedy prostration of the muscular forces—general debility, surprisingly out of proportion to the intensity of the fever and the catarrhal processes. Chill, backache, headache, muscular pain, great debility of physical and mental strength and energy, fever, anorexia and insomnia were the leading or earlier symptoms in almost all well-marked cases; and these indicate the action of a systemic poison, which seemed to have a marked predilection for the nerve centres and mucous membranes, as evidenced in its progress by developing into two well-marked types: the Nervous and the Catarrhal. The symptoms as manifested under the two varieties may be classed in the following symptomatological group:

First. The Nervous Type.—The symptoms are purely nervous, being a continuation of the foregoing initiatory symptoms—minus the chill—with increased severity. Backache, headache, great debility, pains in the limbs and trunk, and frequently painful deglutition, without any disturbance of the respiratory or alimentary tract, save loss of appetite and often nausea. As a rule the severer pain occurred near to, rather than directly in the larger joints, and more generally in the muscles. In the later stages of the disease it often appeared in the lower intercostal spaces, probably by affecting the diaphragm, the patient complaining of being tight, as if bound by a band around the body, or in some single muscle, such as the deltoid, etc. I have seen cases comparatively well in three days, then suffer for six

weeks with severe pain in the left deltoid. Dizziness, sleeplessness, a tendency to fainting and sometimes hebitude, occurred mostly in women, regardless of any conditions peculiar to sex.

Second. The Catarrhal Type.—This was invariably preceded by a similar prodromic stage, and possessed throughout its course marked nervous symptoms analagous to those of the first form—backache, headache, muscular pains, great debility, anorexia, insomnia, etc. In addition to these, it was chiefly recognized by catarrh of the mucous membranes, which again manifested itself in two distinct forms—the bronchitic and the gastro-intestinal; the former being characterized by coryza, sneezing, nasal-pharyngeal and bronchial catarrh, continuing for several days after the initial fever had subsided. The latter by catarrh of the alimentary track, sometimes accompanied by profuse vomiting and diarrhœa.

Both of these varieties were accompanied by a continued fever, the temperature rising rapidly on the first day to 101°, 103° or even 105° F., in due proportion to the severity of the preceding chill, and continuing for several days—usually from one to three days, very rarely longer, where a more or less copious, acid, ill-smelling sweat marked the crisis, which was followed by a rapid decline and convalescence. It is interesting to note, that in all cases of the catarrhal type, a mild sweat preceded the oncoming of the catarrhal symptoms, which usually occurred at the end of the first day, while in those of the nervous type no such phenomenon was noticed. It was the nervous type of this disease, especially, that finished its course in a few days; for the cough and other catarrhal symptoms much more frequently continued longer; and often when they appeared to be going off, they were suddenly renewed with all their former characteristics, by any fresh exposure to cold. Hence, relapses were not uncommon among the cases of the catarrhal variety, while those of the nervous type were comparatively immune. The period of convalescence was very variable, and seemed to depend largely upon the intensity of the attack in both varieties, some persons feeling ready for work as soon as the fever had subsided, while others were unfit for any exertion, felt wearied and depressed, and suffered from continued nervous symptoms for weeks after. The rarer symptoms observed, were chiefly sharp, neuralgic pains, muscular spasms, hyperæsthesia of the skin and a scarlatinoid eruption.

The complications encountered were mainly catarrhal bronchitis, catarrhal pneumonia, dysenteric diarrhœa, otitis, otorrhœa and bronchorrhœa.

The disease was no respecter of age, sex or occupation, the oldest case under my care being eighty-six years old, and the youngest two years old. Of the 513 cases observed, my notes show the following deductions: 327 cases of the nervous type and 186 cases of the catarrhal type of the former variety. There were 287 mild cases and 40 severe cases; and of the latter 131 mild cases and 55 severe cases. 129 cases recovered in three days; 314 cases recovered in eight days; 42 cases recovered in one month; 28 cases lingered for two or three months. Relapses occurred in 68 cases: all of the catarrhal type, with but five exceptions. Of the rarer symptoms and complications, there were noticed the following:

Neuralgic pains, principally in the limbs, neck and face and frequently in the head, like hemicrania, occurred in 297 cases.

Muscular spasms, chiefly in the muscles of the limbs and neck, were noticed in 83 cases.

Hyperæsthesia of the skin of the palms of the hands and of the soles of the feet was observed in one case only.

A scarlatinoid eruption manifested itself in four cases.

Catarrhal bronchitis, complicated, 49 cases.

Catarrhal pneumonia appeared as a complication in six cases.

Dysenteric diarrhœa, profuse and alarming, occurred in two cases, both females.

Otitis, otorrhœa and bronchorrhœa each developed in but one case respectively.

The most interesting of these, to me, was the scarlatinoid eruption.[1] The four cases occurred in the same building—a four-story brick structure, with high ceilings, heated by steam and well ventilated—a boarding school, wherein about one hundred persons congregated daily, including day scholars from the city. Of the seventy persons living in the building, thirty-three were

[1 Dr. Anton Minauf, of Seitenstettin, Austria, publishes in the *Wiener med. Presse*, March 23, 1890, a very interesting communication in regard to the eruption or rash of epidemic influenza—or the Grip—as he and Dr. Wawra observed.—EDITOR OF THE REPORTER.]

affected with well-marked influenza, including the four cases under consideration.

Case 1. Was taken January 19, 1890; temperature 103° the first day, with furred tongue, etc., which continued until the afternoon of the second day, when the peculiar eruption appeared, first on the face, then on the neck and chest and continuing until the entire body was covered. The eruption was decidedly erythematous, of irregularly outlined mottlings at first; but soon coalescence followed, when the appearance was very much like the characteristic eruption of scarlet fever. This eruption continued prominent for six hours, when a profuse sweat terminated the symptoms, and the patient, after a good night's sleep, was discharged and resumed his studies on the following day, January 21. No desquamation followed. Nothing was thought of this eruption in this case, as I ascribed it at the time to the untoward action of the quinine and chloral administered the preceding night.

Case 2. Began January 23, 1890, and on the evening of the same day, the temperature rose to 103½° F. The tongue was coated, with slightly enlarged papillæ; the conjunctivæ and the fauces were very much congested; deglutition was very painful, and there was nausea and vomiting, and an eruption, similar to that in Case 1, began appearing on the face. This being noted, on my first visit, and as no medicine had yet been prescribed or taken, I became fearful of its being a case of scarlet fever. The case was duly isolated, and the nurse was instructed to allow no one to enter the room, which was kept dark, warm and well-ventilated. I prescribed a placebo, and ordered a milk diet exclusively. The next morning my notes show the temperature the same, with all the other symptoms, except that the eruption now covered the neck, chest, abdomen, and the upper part of both upper and lower limbs, presenting the same irregularly outlined mottling. By evening of the second day coalescence was established, and there was a more uniform bright scarlet hue to the eruption, which now covered the entire body. To look at the case was to pronounce it one of scarlet fever, so striking was the resemblance. I now prescribed quinine and chloral in full doses, twenty grains of each at bed-time. A good night was passed, with refreshing sleep, preceded by a profuse sweat (the effect of the quinine). On the third day morning I found the temperature 100° F., the body literally covered with sudamina, the eruption less prominent, and desquamation commencing to take place. The conjunctivæ and fauces were much less congested, and the tongue was almost clean.

The symptoms characteristic of the influenza had abated, as usual, after the action of quinine and chloral. The eruption and desquamation continued jointly in this case until February 2, by which time the eruption had faded entirely, but desquamation continued for about one week longer. The patient convalesced nicely, with full recovery to former health.

Case 3. Started January 27, 1890, the temperature rising to 104½° F. the first day evening. The conjunctivæ and fauces were congested, and the tongue was coated with a thick, yellowish fur, and the papillæ were enlarged. The hearing was impaired, evidently from involvement of the Eustachian tubes. The eruption, though less marked, manifested itself on the face, neck and chest, and grew more marked day by day, having a somewhat venous congested hue and showing less mottling than in the preceding two cases. The sixth day of the disease it suddenly became more intense in scarlet hue, having now covered the entire body, and its bright color continued until February 17, when it suddenly faded after a profuse sweat. It was followed by a crop of sudamina as abundant as in Case 2. In this case desquamation commenced on the fourteenth day of the disease, and continued for four weeks. Otitis of both ears was developed as a complication in this case. Convalescence was very tedious, though the patient made a good recovery.

Case 4. Began February 2, the temperature rising to 100½° F. the first day, with no striking symptoms but those common to influenza. The second day the temperature rose to 101° F., and the eruption made its appearance, quickly passing from the face downward over the entire body. There was conjunctivitis, and the fauces were slightly congested. Desquamation commenced on the third day. The eruption faded on the sixth day and the patient was discharged well on February 7. These four cases presented, in addition to the symptoms enumerated, most of the symptoms common to influenza which marked the other cases. There were some strong points of resemblance between them and dengue and scarlet fever, yet on the whole they were unlike either.

The treatment was generally confined to

the special symptoms as they arose. The morbid condition in itself being self-limited, and the prognosis favorable, it was thought better to care for the symptoms than to attempt to cut the disease short. In the milder cases, nothing was prescribed save rest in bed, simple nutritious diet, a room kept quiet, equably warm to suit the comfort of the patient and well ventilated. During convalescence avoidance of exposure and fatigue was enjoined.

In the severer cases and in the presence of complications the greatest skill was sometimes requisite. The tendency to abdominal congestion and gastric irritability, so frequently prominent in the beginning of the severe cases, was happily overcome by giving from 5 to 10 grains of colomel, triturated with sugar of milk, and following it with a Seidlitz powder or half an ounce of Rochelle salts, dissolved in sweetened water, one hour later. This was given on the first day, so as to secure its evacuating effect before night-fall. Then, if the suffering was severe, from 10 to 20 grains of quinine, in five-grain capsules, was administered on one dose an hour before bed-time, and was followed with from 15 to 25 grains of chloral hydrate, in five-grain capsules, also at one dose, on retiring. The quinine reduced the fever and left its happy equalizing tonic effects upon the system, while the chloral controlled the evil after-effects of the quinine on the head and ears, and produced its characteristic sleep, thus overcoming the insomnia and giving rest to the fatigued body.

The effects of this were so pleasing that the patients frequently declared themselves well on waking the following morning; and indeed they often convinced me that I was almost capable of cutting short the course of the disease.

In severe cases the same injunctions were given as to diet and avoidance of exposure and fatigue, as in the milder cases. During convalescence the best results were obtained from

℞ Liquoris potassii arsenitis . . . . . f℥ij
Syrupi hypophosphitis compositi ad . f℥viij

Listerine . . . . . f℥ij
Aquæ menthæ piperitæ . . q. s. ad f℥iv

M. Sig.: Dessertspoonful in water every 15 to 30 minutes until stools are less frequent; then every two hours.

The case of bronchorrhœa was quickly benefited and cured by

℞ Spiritûs chloroformi . . . . . f℥jss
Acidi hydrocyanici diluti . . . . . f℥j
Tincturæ sanguinariæ . . . q. s. ad f℥iij

M. Sig.: Teaspoonful in sweetened water every 2 to 4 hours.

Notwithstanding the fact that influenza has been known for centuries, its real cause is as much a mystery to-day as it ever has been. Probably at no time was the profession more eager to solve this question than at present, for bacteriologist and sanitarian have been busy ever since the last epidemic began, earnestly searching for a vital cause for influenza; and it is to be hoped that the day is not far distant when the profession will be relieved from this disease. The theories advanced have been formed upon hypothesis, without a single exception. History seems to show beyond doubt, that there are epidemic cycles; that certain periods are broadly discriminated in medical history by the wide prevalence of diseases of this sort. This was recognized as far back as the age of Sydenham, who attributed them to certain unknown changes which take place in the bowels of the earth—*pro varia scilicet ejusdem ætate ac duratione.* Somewhat more distinctly the epidemiologists of a century later attributed epidemic influenza to "cosmical" and the "telluric" agencies, which may also be expressed as those relating to the atmosphere and the *soil:* a division borrowed apparently from Hippocrates. Carrying these upward to higher generalizations, the learned Hæser, in his *Geschichte der Volkskrankheiten* (published in 1839) predicted that the time would come when, to explain the prevalence of these great epidemic periods, men of science would find them more or less in relation to the position of the earth with reference to the plane of the ecliptic, the progression of the magnetic meridian, the alternations in the temperature and moisture

of the earth's surface, the geological changes of water and land, and perhaps even to the progress of the solar system through space. Prof. Leyden, of Berlin, is of the opinion that influenza has sprung from dengue fever —a hybrid; and Prof. Nothnagel, of Vienna, lays great stress on its miasmic character; while others of equal repute are conjecturing on its being due to bacteria.

Does rational thought warrant our accepting such reasoning without substantial facts? We trow not; for there are many reasons which operate against such a desideratum. The poison cannot be dependent upon local surroundings, or upon climatic conditions; for we find that Siberia and Italy have alike suffered, and so have Canada and Mexico, and even Central America. The rapidity with which the disease spreads indicates that the poison is such as can be transmitted by the air; while its pandemic character, the uniformity of the symptoms produced by it, and the evident constitutional involvement, all entitle influenza to rank among the specific diseases.

A few words in conclusion, and I have done. Let us ever be mindful of the fact that man is, in a measure, the servant of the conditions which surround him; but he is not their slave. He must obey them until he understands them; then he dominates them by the divine right of the rule of intelligence over material force. So it will be even with the "Pestilence that slayeth at noonday:" by studying it, he will come to know it; by knowing it, to control it.

THE GRIPPE AS A CAUSE OF ABORTION AND MISCARRIAGE.

BY W. H. BANKS, M. D.,

MIFFLINTOWN, PA.

Since the prevalence of the recent epidemic of grippe, I have been looking eagerly in the columns of medical journals for communications regarding a feature of the disease which to me seems most peculiar, namely, abortion and miscarriage in pregnant women. In one of my cases this occurred after the administration of large doses (three grains four times per day) of quinine; and at the time I attributed the miscarriage to the use of this drug; but, the same accident happening in three other cases that were not influenced by this uterine stimulant, we may very properly conclude that the existing influenza, and not the quinine, was responsible.

The following is a list of cases:

Case 1. Mrs. C., multipara. She had had two normal labors, and one miscarriage, which occurred after severe fright and exposure.

While in the fifth month of pregnancy she was seized with *la grippe* and, during convalescence, began to suffer from severe bearing-down pains and a slight hemorrhage. Under the use of rest and opiates, these threatening symptoms were apparently relieved, but on rising from her bed they again appeared and miscarriage followed.

Case 2. Mrs. J., multipara. She had had two natural labors. The patient was in the seventh month of pregnancy when I was summoned to see her on Jan. 4, and found her suffering severely with facial neuralgia, and also presenting the typical symptoms of *la grippe*. I prescribed quinine, twelve grains per day, and antipyrin in five-grain doses every two hours. The painful symptoms rapidly abated, but on Jan. 8, she fell into labor and was delivered of a well-formed child which, however, lived but three days.

Case 3. K. B., primipara. In the eighth month of pregnancy, while convalescing from an attack of influenza, was seized with severe bearing-down pains and a slight hemorrhage. Under the use of rest, opium and a light vaginal tampon she was finally brought to term and delivered of a healthy child.

Case 4. Mrs. B., multipara. Had had one child and one abortion. She was in the fifth week of pregnancy, when she was seized with *la grippe*. During convalescence she began to suffer from severe pain in her back, thighs and groins and had a moderate hemorrhage. This continued for two weeks, when nausea and vomiting set in, and at this time she sent for assistance. I prescribed tinct. cannabis Indica in elixir lacto-peptino and powders of bismuth and oxalate of cerium, with absolute quiet. However, twelve hours after seeing her, she aborted an ovum apparently of an eight weeks' pregnancy.

—According to the San Francisco *Examiner*, Mr. Adolph Sutro is experimenting with cinchona trees on his estate on the neighboring sea-coast. He hopes to acclimatize at least some of the varieties from which quinine is produced.

Reports of Clinics.

VANDERBILT CLINIC.—NEW YORK. MEDICAL CLINIC.

PROFESSOR DELAFIELD.

Abscess of Liver.

Dr. Delafield referred to the patient who was presented at the Clinic last Thursday in whom he had made the diagnosis of abscess of the liver. The man gave the following history: Last summer he suffered from an attack of catarrhal dysentery (judging from the symptoms). In November he had an acute illness; he was confined to the house and complained of symptoms that pointed to an abscess in some location; since that time he had been steadily growing worse. Though able to be out of doors he was a sick man; he had lost forty pounds in weight. Examination showed the abdomen not distended; the liver did not extend below the free border of the ribs; yet it seemed to fill the hypochondriac region more fully than usual. Posteriorly there was marked dulness over the lower portion of the right lung. The man was admitted to Roosevelt Hospital, and the liver was aspirated, and 1000 c. c. of pus were evacuated. Only the right lobe was affected.

Dr. Delafield remarked that, from our knowledge of the manner of formation of these abscesses, that is, at the expense of the liver substance itself, there must remain but a shell of the right lobe. Hence, notwithstanding the fact that the patient has improved very much and continues to improve, Dr. Delafield is inclined to give a gloomy prognosis.

Subacute Diffuse Nephritis.

The first patient to-day was a man, 38 years old, who said he had been sick since last November. At that time, he says, he "caught cold." He had cough, with expectoration, shortness of breath, and wheezing. He lost flesh, had no appetite, and did not sleep well at night. He did not complain of headache or head symptoms, or stomach symptoms, and had no pains in any part of body. In January he was compelled to go to bed for a few days. At this time his feet swelled a little. Except for this, he has been able to work right along, though feeling that he was a sick man. His urine is increased in quantity, has a specific gravity of 1.010, and contains a large amount of albumin. His temperature is 101°, and his pulse is 126. His body is still fairly well nourished. Physical examination of the lungs gives negative results. The apex of the heart is displaced to the left about one inch, and the heart's action is rapid, regular, and not forcible. A thrill is communicated to the hand placed upon the precordial region. A systolic murmur is heard at the apex, and also at the base—not loud. There is increased arterial tension; but the pulse is in fair proportion to the action of the heart. The skin and mucous membranes are pale. The diagnosis is therefore: hypertrophy of the left ventricle (the murmurs do not necessarily indicate valvular disease) and subacute diffuse nephritis.

The foregoing history is a straightforward one of nephritis; and there is at present still an active process going on. In the same manner it would be wrong to say of a patient with fluid in his chest and an elevation of temperature, that he had simply fluid in his pleural cavity; for in reality he would have an inflammation of the pleura and an effusion. So this man has not chronic, but an active nephritis.

The indications for treatment are, first, to put the patient to bed, where he should remain until the temperature falls, after which, if his condition improves, he could be about the house. Later, if possible, he should be sent to a warm climate. This would not be advisable as long as the nephritis is as active as it is at present.

In the beginning he should be put upon an exclusive milk diet, and Dr. Delafield said that he would test the blood, to find the proportion of hemoglobin, and also to have a positive gauge to the extent of the improvement; for the color of the skin and mucous membranes cannot always be trusted. If diminution of the hemoglobin were found, iron and inhalations of oxygen would be called for. Opium in small doses, would also be of service, particularly for its action as a cardiac sedative. Morphia sulphate, 1/8 gr., four times a day, might be used for two or three weeks.

This patient has been very fortunate in having had so little dropsy. The rule in these cases is to have this a prominent symptom. It is probable that the albumin will persist in the urine for some time to come.

After repeated examinations, should the

specific gravity of the urine always be low, it would be natural to suppose that new connective tissue had been formed in the kidney. One examination would prove nothing.

Chronic Diffuse Nephritis.

The next patient, a man, painter by occupation and thirty-four years old, said he had always enjoyed good health, with the exception of occasional attacks of lead colic, up to one year ago. At this time he began to suffer from headaches. They would come every two or three weeks at first; but lately they have become more frequent. Since January 1, he had almost constant headaches, but less severe than before. These headaches would last from twenty-four to forty-eight hours, and would frequently be accompanied by vomiting and sometimes by convulsions. He would not lose consciousness. Between these attacks he was able to do work until December, when he entered Roosevelt Hospital. Since his last attack, which he had in the Hospital, he has had diplopia.

Examination shows a man fairly well nourished. His pulse is quick, and the arterial tension very much increased. His heart is enlarged, especially on the left side, and a loud, systolic murmur is heard at the base. The ophthalmoscope shows a neuro-retinitis, with hemorrhages in the retina. The urine has a specific gravity of 1.012, and deposits about one-fourth of its bulk of albumin—the same amount as when he first entered the Hospital.

Dr. Delafield called attention to the fact that though this was a case of chronic Bright's disease; yet it presented entirely different characteristics from the preceding case. This was the form in which the structure of the kidney is altered, and in which there is no exudation from the blood-vessels. It is probable the disease has lasted longer than one year: perhaps two or three. At first the only symptoms may have been increased arterial tension and low specific gravity of the urine, with, perhaps, no albuminuria. These signs gradually advanced, and renal symptoms proper set in. Those he suffered from were attacks of acute uremia. They would be preceded by increase in the tension of the blood-vessels, then would come the vomiting, headache and convulsions, and the general health began to fail. The latest advance is found in the neuro-retinitis. The pulse tension remains high, but can be influenced by drugs. As soon as the use of medicine is stopped it relapses to its former condition.

In the treatment of this case the indications are different from those in the last case. Here there is a very chronic process, and there are no acute symptoms. That which causes the most disturbance, at present, is the disorder of the arteries. This causes the uremia. From the inflammation in the kidney directly, there are but few manifestions. It would not be necessary to send this patient to bed; nor would a warm climate offer so much for him; though it might benefit him. His diet must be partly milk and partly solid food. Iron and oxygen are not indicated. Attention should be directed towards relaxation of the arteries. Chloral in five-grain doses, four times daily, might be used at first. If this does not benefit the patient, opium should be tried, in doses sufficient to relax the arteries, one-sixth to one-fourth of a grain of sulphate of morphia may be given four times a day.

Finally, nitro-glycerin may be given three times a day, the dose being one drop of a one per cent. solution, gradually increased to the point of physiological effect, or of tolerance. The skin should be kept in the best condition by frequent bathing and rubbing.

However, in this case the treatment would be, at best, palliative. The man might improve for a time; but the nephritis and the disposition of the arteries to contract would pretty surely advance, until the time would come when drugs would have no effect in diminishing the arterial tension. Then the disease would be near the end.

In both of these cases of nephritis the prognosis is bad; in this one it is the worst.

Tumor of the Pancreas.

The next patient was a man, forty-four years old, who had been before the class last April. He had been sent from the Clinic of Nervous Diseases at that time, with the diagnosis of neurasthenia, and to see if any other disease could be made out. None was discovered, and he was sent back with the diagnosis of neurasthenia confirmed. To-day he was again sent here.

The history he gave when first before the class was that he had had syphilis thirteen years before. Two years ago he commenced to complain of pains in the right side of the back, severe at night and slight during the

day. One and a half years after this the pain was severe day and night. He was pale, had lost thirty pounds in weight, complained of frequent micturition, and had slight œdema of the feet. His urine had a specific gravity of 1.026 and at no time contained abumin. Examination of the blood showed 3,879,000 red blood corpuscles to the millimeter, and 82 per cent. of hemoglobin. The heart's action was somewhat increased; but the physical signs were negative. There was no apparent cause for his sickness.

He was put upon a course of antifebrin and morphine; and his pains left him; but he still was not in good health. Six months ago—about five months after his first examination here—he commenced to notice that his stools were light colored. Three months ago he had pain in the upper part of the abdomen, which has continued. Two months ago he began to have jaundice. He had some nausea, no vomiting. He lost but little flesh. His urine now shows a specific gravity of 1.020, with no albumin, and contains bile pigment. Examination shows the man to be fairly nourished and not very markedly jaundiced.

As he lies upon the table, there is apparent a fulness in the upper part of the abdomen. It is seen to move as he breathes. By palpation, a solid mass is mapped out, which fills the right side of the epigastric region. It is hard and irregular and deep-seated. To the right of this is another tumor, small in size, with apparently fluid contents, in the region of and corresponding with a distended gall-bladder. The former tumor, which is nearly the size of the fetal head, is somewhat movable, and is connected either with the pylorus or with the head of the pancreas or the wall of the common bile-duct.

Dr. Delafield did not think it felt exactly like a tumor of the pylorus; it seemed too deep-seated, and was not as freely movable as these growths sometimes are. And again, a tumor of the pylorus of that size would produce gastric symptoms, and would have more effect on the patient's nutrition—though some patients with this condition do thrive wonderfully.

The new growth presses upon the common bile-duct, and hence the distended gall-bladder and the jaundice. All things considered, Dr. Delafield was of the opinion that it was probably a malignant growth from the head of the pancreas; and he believed that it was not present when he examined the man last April, and that it had existed about six or eight months.

PERISCOPE.

Operations for Hernia in Children.

Mr. Edmund Owen, in speaking on the subject of hernia in children, in a lecture delivered before the Medical Society of London, and reported in the *Medical Press and Circular*, Feb. 12, 1890, said that there are some herniæ with which it is beyond the power of the surgeon successfully to deal with any truss whatever; the protrusion may keep up for a short while, but as soon as the child begins to get about it slips down again, and lies compressed beneath the pad. If a truss with a stronger spring be employed the pressure becomes intolerant or the skin is chafed. The medical attendant and the parents grow weary of the case, and the child is allowed to go about with a certain amount of bowel in the scrotum—an amount which generally becomes an increasing quantity. To offer an equally unsatisfactory state of affairs, though the hernia of another child is not large nor particularly unmanageable, his parents are too poor to supply him with the necessary apparatus, and too ignorant or careless to give the necessary help in making it available.

What, asks Mr. Owen, is the proper course to adopt with regard to such children? "What is their exact age?" some one may ask. This has very little influence on the question, when we have to do with ruptured children who cannot, for one reason or another, be satisfactorily dealt with in what one may call the gentle method—that is without operation. "But," rejoins the inquirer, "you surely will not advise a cutting operation for the cure of a reducible hernia in a very little child!" The surgeon's reply is that it is his duty to cure the child, and if he cannot do so in a bloodless way he must submit the child to the risk of a cutting operation. And now comes a very important point in the consideration of the question, and one of which we must not for a moment lose sight when estimating the risks of the radical treatment—unless the boy be solidly cured of his hernia he will be every day of his life in peril of a knuckle of bowel becoming strangulated. And if the strangulation occurred at a time when,

and at a place where, adequate assistance is not forthcoming, or if the child—now grown into manhood, and always careless of himself—fail to call in surgical aid until the intestine has become tightly pinched for some hours; what about risk? Here, surely, is a terrible risk; yet it is the same patient, the same open funicular process, and the same hernia with which we had been dealing years before. Unfortunately, though we have diminished risk in connection with the practice of our art, we have not entirely abolished it. Indeed, every important step through life is associated with risk, and surgical progress can never be freed from it. And though we must never allow ourselves or our patients to think too lightly of surgical risk, still we shall do well in encountering it in such circumstances as we are able to select, not in those which blind chance would force upon us.

Of course, there will be some badly-ruptured children who are not suited for the radical operation—the feeble, sickly, ill-nourished and imbecile. Sir Joseph Lister has rightly said that the judicious selection of cases is an antiseptic measure, and certainly if we are to get the best results for the operative treatment of congenital hernia we must exercise considerable discretion in the choice of our subjects.

Sometimes we hear the operative treatment spoken of as the "radical cure." Radical *treatment* it is, and cure it may be; but to talk of it as the "radical cure" is to surround the procedure with an attractiveness which may mislead the parents of the child and disappoint the inexperienced operator. I cannot attempt to say in what percentage of cases in childhood the radical operation fails to cure the hernia, and statistics which may be prepared from the published reports can, for obvious reasons, be barely approximate. Surgical statistics which are taken over general areas, are never of much use, for the collector cannot take into due consideration such important factors of the nature of original defect, the capacity as the operator and the physical value of the patient.

The open method of the treatment of congenital inguinal hernia is based upon a very solid ground, inasmuch as it is designed simply to make good a defect which Nature had omitted efficiently to deal with. At, or shortly after birth, there should no longer be a tubular communication between the peritoneal cavity and the tunica vaginalis; should the passage remain wide open a piece of bowel is more than likely to enter it, and, having once descended into it, the task of keeping it out by a truss is, as we have already admitted, sometimes one of great difficulty, and in rare instances a practical impossibility. These last are the cases for which the open method is needed.

Effect of Gastric Juice on the Tubercle Bacillus.

Zagari (as reported in the *Centralblatt für Bakt. und Parasit.*) has recently performed a number of experiments for the purpose of determining the action of gastric juice upon the bacillus of tuberculosis. After feeding dogs with excrementitious matter from tuberculous patients, and also with the organs of those dead of tuberculosis—both being proven to contain bacilli in abundance—he found that so far from suffering damage from their unwholesome diet, some of the animals even became fat upon it. The excrement of the dogs on examination proved to contain bacilli in perhaps greater numbers than that fed to them. Inoculations with these sufficed to infect guinea pigs with tuberculosis, showing that the bacilli had well resisted the action of the gastric and intestinal fluids. This is the more noteworthy, since the acidity of the gastric juice of the dog is high.

Zagari also submitted tubercle bacilli to the action of gastric juice outside the animal organism, with the following results:

After from 3 to 4 hours' exposure at 38° the bacilli still possessed their full virulence.

After from 18 to 24 hours their virulence was completely lost.

After from 6 to 8 hours' exposure, their virulence was somewhat diminished, the disease following inoculation of guinea pigs very slowly.

After from 7 to 9 hours a local tuberculosis alone could be established.

The acidity of the gastric juice of the dog equals 0.159 per cent.; that of gastric juice of consumptives whose excrement was used equals 0.0675 per cent; that of gastric juice used in subsequent experiments equals 0.1652.

These results of Zagari agree very well with those obtained by Straus and Wurtz (see MEDICAL AND SURGICAL REPORTER, March 8, 1890), who exposed various pathogenic organisms, amongst others, that of tuberculosis, to the action of gastric juice,

having the same object in view as Zagari. Their experiments were all made outside the animal organism. Gastric juice was taken from dogs, men and sheep, and the bacilli were exposed to it at a temperature of 38° C.

Judging from these results, we must come to the conclusion that so long as the gastric juice retains a sufficient degree of acidity, tuberculosis of the alimentary canal will be unlikely to occur. The practical application is not far to seek. We must, by some means, keep the gastric juice of tuberculosis patients in its normal condition as regards acidity, or even increase it, so far as compatible with good digestion. — *Canadian Practitioner*, April 1, 1890.

Oatmeal Snares.

We have nothing to say at present concerning the numerous vaunted benefits of oatmeal as a food commodity, and, indeed, there can be no doubt that good oatmeal, properly prepared, is of benefit to the human system. But the question arises whether it is not a fact that in our present age of hurry and the desire to do things quickly, many people injure their digestive organs by eating oatmeal not sufficiently cooked, and, therefore, in a condition in which the digestive fluids cannot act upon it, leaving it undigested simply to act as any foreign body would act in the system, as a violent mechanical irritant. We are forced to this conclusion by the now too prevalent advertisements of oatmeal prepared by different manufacturers, and claimed to be so prepared as to enable it to be cooked in from three to five minutes. This is simply an impossibility. These kinds of so-called oatmeals are simply decorticated oats, which before grinding are steamed. This steaming destroys any low organisms that may be in the oats. A little bicarbonate of soda and lime is added to help dissolve the albuminoids, and in some instances diatase to increase the converting power of the starch to sugar, but there is nothing in this process that can, in our opinion, so alter the chemical nature of oats or oatmeal as to make it possible to cook it ready for easy digestion in three or five minutes. Against this snare and delusion we would warn the reader. While thoroughly cooked oatmeal, cooked in the good old-fashioned way, is no doubt a nutritious dish, these deceitful and misleading prepared oatmeals are a constant source of great danger, and, to be on the safe side, avoid them.—*American Analyst*, April 3, 1890.

Aristol.

At the meeting of the Société de Thérapeutique of Paris, held March 12, 1890, and reported in the *Progrès Médical*, March 22, 1890, Dr. Boymond read a paper on the subject of aristol. As a remedy in skin diseases aristol is claimed to be an efficient substitute for iodoform and iodol. It is innoxious and odorless. The substance is obtained in the form of a brownish red precipitate, by treating a solution of iodine in iodide of potassium with thymol dissolved in caustic soda. Aristol is properly a biniodide of dithymol. It is insoluble in water, slightly soluble in alcohol, and easily so in ether. It may be applied in mixture with fatty oils, or as a powder to wounds and burns. It is not absorbed into the system, and no toxic action has ever been observed to follow its use. It is as efficacious as chrysarobin in the treatment of psoriasis; but it does not stain the skin nor produce conjunctivitis.

The following formula for aristol salve is recommended by Eichoff:

℞ Aristol . . . . . 3–10 parts;
Vaseline . . . . . 30 parts.–M.

It is well, after application of the ointment, to cover the affected parts with protective or rubber. The drug may be applied two or three times daily.

The Pneumatoscope.

An instrument, designed to render more audible the sounds produced by pulmonary percussion, was presented to the Berlin Medical Society at its meeting, held February 26, by Dr. Gabritschewsky, of Moscow. The instrument consists of two funnel-shaped cones, joined at the smaller ends. One of the openings fits over the patient's mouth and the other is provided with a diaphragm and is connected with the operator's ears by rubber tubes. The patient, during examination, is instructed to keep his mouth open and to breathe through the nose. The sound waves, produced by percussion, are, somehow or other, reproduced on the diaphragm.

Judging by the comments made by the members of the Society who spoke after Dr. Gabritschewsky, the instrument was not regarded by them as one of great value.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

ANTISEPSIS IN VACCINATION.

When Jenner first inoculated for the prevention of small-pox, now over one hundred years ago, the possible occurrence of dangerous or even fatal complications was recognized, and anti-vaccinationists used this fact as their strongest argument against the practice. Cases of erysipelas and septic infection have occurred only too frequently ever since. In a large number of instances these accidents have been attributed to "bad lymph." Even in these days of advanced antiseptic surgery fatal results following vaccination are not infrequently reported, while erysipelatous complications are of so frequent occurrence as to be hardly deemed worthy of record.

Antisepsis, however crude, is but rarely practiced in vaccination. In the REPORTER for May 12, 1888, attention was called to this fact, and a thorough scrubbing of the field of the operation was recommended. As a rule, the operation consists in baring of the patient's arm and immediately introducing the lymph, while, as soon as the blood dries, the sleeve is pulled down.

The possibility of septic infection being so well known, there can be no excuse for the physician failing to use strict antisepsis in vaccination, simple though the operation be. The parts should be first washed and scrubbed with a brush, using hot water and soap. This will remove all the superficial dead epidermis. The antiseptic toilet may be completed—if this seems worth while—by washing the parts with alcohol or any antiseptic solution. The lancet used should be perfectly clean. The after-treatment is of no less importance. After vaccination the abrasion should be covered with pad of boracic, or eucalyptus absorbent cotton. This will keep the limb from injury as well as prevent infection from without.

In discussing this plan of treatment in the *British Med. Journal*, Feb. 1, 1890, Mr. John Bark advises that the pad should be covered with antiseptic gauze, with the exception of its inner surface. It may be kept in place by two straps of soft half-inch tape passed around the arm, while another strap, fastened to the upper border of the pad and passing under the opposite axilla, will prevent its slipping down. Mr. Bark, however, does not apply the pad until after opening the vesicle on the eighth day, claiming that before this time, according to his own experience, septic absorption does not take place. The mother or nurse should be warned not to disturb the dressing for at least six days; when it will be found, even in cases in which there has been a large inflammatory areola, that after the removal of the pad, all inflammatory infiltration will have entirely disappeared, and, in most cases, a hard, firm scab will have replaced the vesicles.

The pad has the advantage over ordinary shields, that, besides protecting the arm

from external violence, it also absorbs all the discharge and minimizes the risk of septic absorption. Ordinary shields should not be recommended since they can be used more than once and might thus easily carry infection.

It may be argued that these precautions are not called for, and will take up too much of the physician's time. But it will be found in practice that the suggestions just given can be complied with without any serious loss of time. But even if they did take some time, any method which may accomplish the abolition of such accidents in vaccination as septic infection and erysipelas is surely worthy of trial and consideration.

ADVANCE IN MEDICAL EDUCATION.

We have recently, on several occasions, referred editorially to the marked desire for an improvement in medical education, evinced by the profession in America. The movement for an extension of the medical course of study, and for a careful preliminary education is gradually becoming general. Universities, colleges and societies from all parts of the United States are joined in this laudable work. Among the colleges that have most recently extended their courses is the Starling Medical College, of Columbus, Ohio, which has determined that three courses of medical lectures shall be required of candidates for graduation, after the session of 1890-91. The Faculty of the Hospital College of Medicine, Louisville, Ky., has adopted a rule requiring all students after the sessions of 1891 to attend three courses of lectures in separate years as a condition precedent to graduation.

Our brethren in New Jersey are working towards the same end. The Camden Medical Society has appointed a committee to urge upon the New Jersey Legislature the passage of the Kalisch Bill, providing for the establishment of a State Medical Examining Board. The profession in Rhode Island has also been aroused to activity. A bill to regulate medical practice in Rhode Island is now before the Legislature of that State. The first section of the Act provides that only registered physicians shall be allowed to practice medicine in this State, and Section 2 is as follows: "Every person in order to be a registered physician within the meaning of this Act shall be either a graduate in medicine or a practicing physician. Graduates in medicine shall be such as have obtained a diploma from a regularly incorporated school or college of medicine, and shall have presented to the State Board of Medicine satisfactory evidence of their qualifications. A practicing physician shall be deemed to be a person who for the —— years next preceding the passage of this Act has continuously practiced medicine in this State, and who shall have presented to the State Board of Medicine satisfactory evidence of his qualifications, and any other person who shall have presented to the State Board of Medicine satisfactory evidence of his qualifications to practice medicine." We sincerely trust that both the Legislature and the Governor of Rhode Island will recognize the importance of the bill and that it will speedily pass.

In Oregon a similar bill, called the Power Medical Bill, was recently passed by the Legislature of that State, but was unfortunately vetoed by the Governor, who gave as one reason, that it did not recognize sufficiently the different schools of medical practice. A new bill has now been introduced, which, it is hoped, will prove acceptable to the Governor.

The necessity for a graded course of study in any branch of science is apparent, but it is especially urgent in the study of medicine, with all its bewildering complexities, and as yet but half discerned truths. It is, therefore, appalling to estimate the number of comparatively illiterate men who, during recent years, after a few months of desultory study, and in the face of the present advanced state of the science of medicine, have attained, in colleges in this country,

legally if not meritoriously, the honorable title of "Learned in Medicine."

It is the duty of every medical organization to stimulate and endorse every effort of State or Society, directed towards the correction of the existing faults in medical education, and the furtherance of advanced methods; and now that the profession has been fully aroused to the desirability both of an extended course of study and of a preliminary training, the establishment of both should be striven for in every city and State.

We trust that ere long this will be the case, and also that every State shall have a competent medical examining board, and that the medical profession in the United States will be elevated to its legitimate position. It will always be the policy of the REPORTER to give this most important subject prominence, and to report to its readers every advance made in this direction.

PUNCTURE OF THE INTESTINE FOR OCCLUSION.

At the last meeting of the French College of Surgeons, Professor Demons, of Bordeaux, advocated the practice of making punctures into the intestine in the treatment of chronic occlusion of the bowel, and deprecated the unmerited disuse—as he thinks it—into which this method has fallen. Among the advantages which he claims for it, is the fact that after relieving the bowel of the gas which has inflated it, it is often possible—on account of the flaccid condition of the belly-wall—to determine the cause of the occlusion and to institute intelligently some other procedure to overcome or remove it. Professor Demons speaks of the operation of puncture as being only a palliative measure, and yet he reports six cases in which it was followed by permanent relief of the condition of obstruction. One of the most striking features of his communication was the statement that he has never seen any ill-effect to follow the making of punctures in the bowel; while in the most unsatisfactory cases it gave at least temporary relief to the patient.

These opinions of Professor Demons were published in the French medical journals as long ago as last October; but they do not seem to have attracted the attention which they deserve. He speaks of a sort of revival of the method in England; but this is somewhat of euphemism; for in England, as in this country, most surgeons regard such a procedure as in the highest degree dangerous. There and here, we believe, there is hardly a surgeon who would consider it justifiable to puncture the intestines except in extreme cases, and in the face of impending death from suffocation caused by pressure of inflated intestines upon the diaphragm.

Nevertheless, it may be that there is something to be said in favor of aspirating the intestines, and that this is not so dangerous as most surgeons think. There are times when the relief furnished by such a procedure may be of the greatest advantage. Not long ago, in Philadelphia, a woman, dying in consequence of a fracture in the cervical portion of the spinal column, who was being suffocated in consequence of the accumulation of gas in the intestines, was relieved by means of puncturing the intestine with a fine aspirating needle sufficiently and for a long enough time to make a will. In another case a patient dying of peritonitis was relieved so much as to encourage the belief that the operation had proved of great service in lessening the discomforts of his inevitable death.

In cases of this sort we believe that puncturing the intestines is a measure which ought to be resorted to, and can believe that in some cases it may prove of more than temporary utility. Certainly the very strong and positive statements of Professor Demons suggest that there may be too much dread in the minds of surgeons in regard to this procedure, and that it may have a field of usefulness which warrants a more general consideration than it has heretofore enjoyed.

ESSENCE OF CINNAMON AND TYPHOID FEVER.

The newspapers of April 19, 1890, report, under the heading, "Highly Important, if True," that a discovery of vital importance has just been made by Dr. Chamberland, Pasteur's assistant, and Drs. Mennier and Cadéac, which proves that essence of cinnamon, when sprinkled in the rooms of a typhoid fever patient, kills the bacteria within twelve hours and prevents the disease from spreading.

This curious item may have originated at Pasteur's laboratory; for many strange things have come from that source; but it would probably be unjust to charge it with one which displays so many different marks of ignorance as this one in regard to typhoid fever does.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

ANÆSTHETICS, ANCIENT AND MODERN: Their physiological action, therapeutic use and mode of administration; together with an historical *resume* of the introduction of modern anæsthetics—nitrous oxide, ether, chloroform and cocaine; and also an account of the more celebrated anæsthetics in use from the earliest time to the discovery of nitrous oxide. By George Foy, F. R. C. S., Fellow of the Royal Academy of Medicine in Ireland, etc. 8vo, pp. 175. London: Ballière, Tindall & Cox, 1889.

The greater part of this volume has appeared in the shape of monthly contributions to the *Dublin Journal of Medical Science*, during the years 1888 and 1889. The author states in his preface that his object in undertaking the work was not to rob the men of the present day of discoveries rightfully theirs, but to give credit, where credit is due, to the ancients. He has endeavored to bring from the relics of the almost forgotten past whatever may tell of the gradual evolution of the anæsthetics of to-day from the first crude attempts of ancient medical men to find a suitable analgesic. Mr. Foy divides the history of anæsthetics into three periods: First, the period of crude drugs, which lasted until the discovery of distillation, and was associated with superstition often of a gross character; second, the period of distilled products, which lasted until the isolation of oxygen; from which event may be dated, third, that of the inception of the discovery of modern anæsthetics.

The history of the use of various agents to relieve pain, as related by Mr. Foy, is extremely interesting. It is evident that the ancients were familiar with mandragora, opium, and cannabis Indica, and perhaps they actually used, in some instances, anæsthetic gases. The story of chloroform and ether is more familiar to most persons. Americans will be glad to know that full credit is given them for the discoveries of Guthrie and Jackson. Regarding the safety of chloroform, even in patients with heart disease, the author quotes Dr. Lawrie's opinions concerning the experiments performed by the Hyderabad commission, and also quotes freely from our countrymen, Drs. Hunter McGuire and Chisolm. Throughout the book he shows an appreciative familiarity with the contributions of American writers. Some useful general rules for the administration of anæsthetics are given in Chapter XIV.

Dr. Foy has made an interesting collection of historical references to anæsthetics, and has grouped together some valuable observations on the more important of them now in use. The book is written in a pleasing style, and a manifest spirit of fairness pervades it. Altogether the book is instructive, and it fulfils a useful purpose.

A HAND-BOOK OF DISEASES OF WOMEN, INCLUDING DISEASES OF THE BLADDER AND URETHRA. By Dr. F. Winckel, Professor of Gynecology, and Director of the Royal University Clinic for Women in Munich. Authorized Translation. Edited by Theophilus Parvin, M. D., Professor of Obstetrics and Diseases of Women and Children, in Jefferson Medical College, Philadelphia. Second Edition, Revised and Enlarged, with 150 Illustrations. 8vo, pp. 756. Philadelphia: P. Blackiston, Son & Co., 1889. Price, $3.00.

The character of Winckel's Hand-book of Diseases of Women is so well known as not to need extensive notice. The author is a recognized authority, and a man of great learning, wide experience and conservative judgment. The book is what we should expect from such an author.

The present edition contains a section upon the diseases of the bladder and urethra in women, derived chiefly from Winckel's monograph upon that subject.

As placing before English readers the views of Winckel, the Editor and Publishers are to be congratulated for issuing the work. But the student and practitioner must bear in mind that the opinions expressed are not recent, and that in the sections devoted to subjects in which rapid advances have been made, the accepted teachings of to-day are not set forth. This refers more especially to the sections devoted to pelvic inflammation and abdominal surgery.

It gives us great pleasure to add that this fact is frankly stated in the Editor's preface. The thoroughly scientific character of the work gives it such value that it will be an addition to any library.

Correspondence.

Pseudo-encephalic Monster.

To the Editor.

Sir: In the Reporter of Jan. 18, 1890, appears an article entitled "Pseudo-cephloid Infant," the description tallying so closely to my experience that I have decided to put it in print for the benefit of my brothers who are just commencing to practice.

In August, 1887, I was called to my first case of confinement. The patient was Mrs. B., 35 years old. She had before given birth to five well-formed children, all of

whom were living at the time, the family generally in the best of health. I took my seat beside the mother, asking many questions, and learned from her that she had but little trouble in her previous confinements. I felt quite encouraged, as I had not made an examination. After a few minutes the mother complained very much of the movements of the child, they being very strong and spasmodic—more so than usual, as she never had experienced such movements in her previous confinements. I made an examination and found, as I thought, the vertex presenting; but at the same time I felt a mass of substance that I could not make out. I kept my own counsel, only assuring the mother that the head was presenting, and that everything would be over in a short time. It seemed to me that my hair was standing on end, and the chills began to creep up and down my spine, and I thought of a hundred different things that had been taught by the professors of obstetrics. But none of them seemed to fit this case. I felt backward in making the second examination for fear of the mother's reproach, should I tell her some other part was presenting, and that the labor might be tedious, or that instruments might be required. I put on a wise look, and made the second examination; but found no progress. The pains were now few and weak, but the mother seemed to be in the best of spirits. I waited thirty minutes. Labor at the time seemed stimulated, and I made my third examination. The head had come down, allowing me to make a good examination. Again I came in contact with the peculiar mass, and the chills resumed their movement up and down my back. After considerable manipulation I could feel sharp edges of bone surrounding the mass; and the puzzle seemed to deepen. Further examination brought the depression of the root of the nose and eye within reach of my finger, and then I was sure the head was presenting; and I felt greatly relieved. But what to think of the soft mass was still a mystery to me.

After several hard labor pains a male child, well formed except as to the head, was born. It weighed eight pounds. Respiration was established immediately; and the pulsation was good. The child made several peculiar sounds, but could not nurse, and lived only eighteen hours.

The frontal, the parietal, and the squamous portion of the temporal bones were absent. The eyes remained open. The soft mass was of a dark red color, resembling liver. It was covered with a dense membrane, dipping down and dividing the mass into five distinct sacs, which were filled with fluid. No brain substance could be distinguished. The child was carried to full term. I was not allowed to make a minute examination, and a fuller description of the mass cannot be given. To say I felt relieved at the easy termination of the labor is putting the matter very mildly.

Yours truly,

B. F. Harding, M. D.

Crestline, Ohio.

Strange Remedies.

To the Editor.

Sir: A Mr. Haw, writing from South Africa to the London *Lancet*, describes some of the remedies relied on by the people of Transvaal. They are not new to me or original with that people. Twenty years ago I began practice near the foot of Lake Champlain, and most of the remedies mentioned were in vogue there. They are survivals of medicine handed down from their common Dutch ancestors. Many of these old absurdities may still be found in America among the descendants of any European nationality.

Cow-dung poultice, which he mentions, is in very common use. Turning to Salmon's *London Pharmacopœia* of 1620, I find it there quoted as a standard remedy, not only for external but also for internal use. He gives a formula for *Tinctura Sterci Bovis*. "It is of a cleansing faculty, temperate in quality and a great Anodyne. Good against all diseases." Several preparations follow: one of which is *Hedychrum*, "Perfume of cow-dung, gathered in May, June or July and distilled. Cooling, discussive, carminative."

He speaks of a young goat killed and immediately opened, into which a child is put. He does not mention for what disease, presumably for pneumonia, as I have seen it done, except that it was into a sheep instead of a goat. For peritonitis a common remedy is to cut open a live black hen and apply it to the abdomen. For sprain, the warm entrails of a sheep or hog.

Eel-skin strings or strips he mentions as used for rheumatism. I have seen many men wearing these strips about their wrists and ankles for stiffness there. It is a com-

mon practice in the by-ways of New England to tie a hank of flax or a skein of linen thread around the waist of a child having mumps "to prevent them from going down." I do not find this in Salmon.

Mr. Haw saw them use the finely chopped hairs of a black cat that had no trace of white on it, mixed with sugar, for convulsions. I have known this to have been given for worms, and also found a patient's breast that threatened to suppurate covered with an ointment made with the hairs and lard.

The blood from the black cat is often applied as a remedy for shingles.

This is in the old *Pharmacopœia:*

"Fowl-poultice for snake bite." It was commonly used for dog or cat bite. In Salmon's *Dispensatory* it is written, "the Anus of a live Fowl applyed to a Bubo draws out the Poyson, by its attractive quality." For jaundice, scoop out a carrot, fill it with the urine of the patient and hang it against the back of the chimney. When the urine evaporates, the person recovers. I was called to see a patient for which the remedy had failed. The old lady said it was useless, unless done in the dark of the moon.

Children still practice counting warts to make them disappear; but I had supposed hanging them in effigy was original with my community. I have seen the chimney-back many a time decorated with a rude drawing of a gallows with ropes dangling and knotted ends to represent the warts. When the smoke effaced this the warts disappeared.

For wounds made by a nail or splinter, to wrap the implement in a soft cloth and to lay it in a warm place, is a common practice. Last summer I saw the village farrier carefully wash a horse's wound, made by a barbed-wire fence, then lay in it two small sticks cut from a sweet apple tree; these he then wrapped in a paper and placed them carefully over the kitchen stove. No other treatment was given to the ugly wound. He said he had practiced this for forty years, sometimes on men, and had never failed of a successful cure. It was a queer reminder of the sympathetic powder of Sir Kenelm Digby, with which the sword was anointed and carefully dressed for the cure of the wound. King James I gave him a large reward for it (1658).

There are many new things under the sun nowadays, but there are many of the old things surviving. Yours truly,

P. J. F.

Clinton, Iowa.

Notes and Comments.

The Commitment of the Insane to Asylums and Hospitals.

At a meeting of the New York Neurological Society, held February 4, 1890, a committee, appointed at the preceding meeting to examine the proposed new lunacy law, known as the Gallup Bill, reported that the measure has a large number of very excellent features, which, if they should become law, would prove of the highest advantage to the unfortunates whom they are intended to benefit. These are the sections relating to:

1. The removal of the insane to asylums by attendants of the same sex.

2. The admission and discharge of voluntary patients.

3. The admission of emergency cases without papers of any kind for three days.

4. The forbidding of the confinement of insane persons in jails in the same room with criminals, and any detention beyond ten days.

5. The provision of home visits of indefinite duration at the discretion of the medical officers of the asylums.

6. The boarding-out of suitable chronic lunatics in private families, at county expense, according to the systems in vogue in Scotland and Massachusetts.

Aside from the invaluable particulars just described, there are several sections relating to commitment to which there would seem to be serious objections.

According to the present law, the family physician calls in another physician. Together they make out two medical certificates and swear to them before a notary. (This is all sufficient for admission to the asylum for five days.) A judge of a court of record must write his name and the word "approved" on the back of the certificates to make them valid beyond the five days. The papers must not be over ten days old when the patient is admitted.

According to the proposed law, the family physician makes out a formal paper notifying a judge, justice of the peace or superintendent of the poor that a patient of his is insane and a proper subject for an asylum. The official thus notified fills out two blank forms directing two physicians to examine the patient. The physicians make out two medical certificates, which are returned to said official. If the officer notified be a justice of the peace or superintendent of the

poor, he must himself also visit the patient and satisfy himself as to his insanity, after receiving the certificates of the physicians. He then makes out himself a corroborating certificate, and presents the three certificates to a judge of a court of record. The judge then sends notice to the patient of the proceedings, makes out an order committing him to the asylum, and finally issues a warrant to the asylum superintendent to send for the patient, or to a county official to remove him thither. The judge must also cause copies of the medical papers to be filed in the office of the county clerk; and he must furthermore take proof as to the estate of the patient, filing another certificate as to these facts with the county clerk. The process is only completed after a formal paper has been made out by the asylum superintendent to the judge committing the patient, notifying him of the admission of the case. The judge must cause this paper also to be filed with the other papers in the office of the county clerk.

At present two papers only are necessary for the commitment of a patient to a hospital for the insane. According to the law proposed thirteen papers will be required; and simplified as much as possible by avoiding the lower officers and applying directly to the judge of a court of record, twelve papers, according to forms prescribed in the bill must be made out before the legal process is accomplished.

The objections to this form of procedure are:

1. It is unnecessarily complicated.

2. The position of Examiner in Lunacy will be degraded to a reward for political labors.

3. Patients will suffer harm from the visitation of two strange physicians, of the county official or judge, and of an officer of the court with a notification of the legal proceedings about to be instituted.

The committee says that, simple in comparison as is the existing law of commitment, no person has ever been, through intentional wrong-doing, placed in an asylum as insane in New York State. But it is possible to make certain improvements in the law now in force, not only in the manner of commitment, but also in the means of regaining subsequent liberty; and the committee submitted the following suggestions:

1. There should be no material change in the present mode of commitment by two medical certificates, sworn to, and approved by a judge of a court of record, as provided in the Laws of 1874.

2. Emergency cases should be received for three days without papers of any kind, as specified in the proposed new law.

3. The medical certificates should be more carefully and thoroughly made out, not only in justice to the patient, but also for the benefit of the asylum physicians, who now rarely receive many facts bearing upon the medical history of their patients or upon their mental condition. To this end the form prescribed in the Gallup Bill should be adopted. A few additional questions should be incorporated in the medical certificate for the purpose of determining whether the physicians have informed the patient of their intention of placing him in a hospital for the insane for treatment, in order to guard against the serious harm so often done to patients by removing them to an institution through deception. The State Commission in Lunacy seems to be invested with the power to prescribe the form in which the medical certificate should be made out, and a law regulating this would not appear to be necessary.

4. There should be a section in the law permitting any higher justice, upon application from any patient in an asylum, to appoint at his discretion a commission of two or three physicians to quietly examine said patient as to his mental condition, and upon receiving their report favorable thereto, to discharge him from the custody of the asylum.

5. A clause should be introduced into the bill providing that nothing in the lunacy laws of the State shall be construed to interfere with the reception and treatment of acute cases of insanity in chartered general hospitals, in the same manner and under the same conditions as patients suffering from other diseases are there received and treated, provided such hospitals have suitable accommodations approved by the State Commission in Lunacy.

Diphtheria—its Treatment.

In the *North Carolina Med. Journal* for March, 1890, Dr. E. B. Goelet, of Saluda, N. C., has an excellent practical paper on diphtheria, in which he says:

The symptoms vary from simple sore throat to complete constitutional prostration. Usually there is, at first, a malaise or tired feel-

ing, with loss of appetite; next the throat becomes sore, and there is languidness with fever; then the eyes get dull, showing constitutional depression and feebleness; the tonsils are only slightly enlarged out of proportion to the constitutional symptoms; then appears a general redness of the palate, pharynx and tonsils, with dusky reddened blotches and white or ash-colored spots, spreading rapidly and developing in glandular enlargements; the inflamed surface exudes false membranes containing micrococci, which inoculates all other surfaces in contact therewith; and finally the disease expresses itself anywhere on the body there is an abrasion. If let alone the tendency is to death by suffocation, on account of the spread and rapid growth of these false membranes. The involved cervical glands increase enormously. Blood-clots may form and attach themselves to the valves of the heart, then be swept off as emboli.

In tonsillitis there is a sharp attack of fever, high temperature and enlarged tonsils, with no history of malaise, the eyes are bright, there is no languor or prostration, the swelling and redness confined to the tonsils.

In follicular tonsillitis there is no fever, no constitutional depression, but very enlarged tonsils on both sides, covered with patches in the depressions of the tonsils, but these patches are superficial and easily removed; in a day or two, under proper treatment, the patches reduce in size and soon disappear.

In scarlet fever the symptoms resemble diphtheria, but the eruption appears in the first twenty-four hours, the throat symptoms come on later, and the redness is scarlet and diffused.

In diphtheria the fever is slight, of low grade, resembling an asthenic type, the eyes are dull, and there is constitutional depression, simple enlargement of the tonsils, inflamed palate and pharynx, with whitish spots or patches appearing upon a reddened base, the spots are adherent and apt to cause a flow of blood when removed, there may be an eruption, but that comes on later; the early symptoms are confined to the throat, the patches spread rapidly and inoculate all surfaces in contact with them.

The treatment should be based upon constitutional theory. A proper germ poison put into the blood will arrest its development and destroy the membrane. Sulphur and chlorine are the most potent germicides known. Now we want to get sulphurous acid into the blood; and, in order to do so, we give the sulphite of sodium. It will not hurt the patient, but will destroy the germ and be excreted by the kidneys as a sulphate. From twenty to thirty grains taken every two hours will keep up a continuous action; large doses act as a purgative, but do no harm. As a local application, use chlorine water. I usually generate it in this way: Take chlorate of potash, ʒij; and hydrochloric acid, [The writer probably meant to say *sulphuric* acid. Ed. Reporter.] ♏xx; put into a well-stoppered eight-ounce vial, and when decomposition has taken place, add through a glass funnel, glycerine fʒii, to absorb the chlorine; then add water to fill the vial. Use this as a gargle, and it will clean off the membrane as a wet sponge does a slate. It can be even given in doses of fʒi every three hours. As a prophylactic, I prefer the sulphite of sodium; for chlorine is a powerful cardiac stimulant and diuretic, and is best suited to severe cases. I have had a number of cases this fall and winter and have lost only one.

I have a firm conviction that, if called to see the patient in time, with this treatment there should be no fear as to the result.

Absence of Malaria on the Eastern Shore of Maryland.

In a pamphlet on the Climate of the Eastern Shore of Maryland, Dr. C. W. Chancellor, Secretary of the Maryland State Board of Health, says that for a long time the Eastern Shore of Maryland has rested under a reputation such as is likely to arise from a careless observation of her physical constitution and relations; but the light of investigation and experience has in a measure dispelled this belief.

The salubrity of any particular locality cannot always be exactly interpreted from local conditions, or a mere string of figures be said to represent meteorological phenomena. They are, however, very valuable in conjunction with other knowledge; and any information obtained from intelligent physicians and other persons who have lived long in a place, as to its general salubrity is valuable in forming a judgment of the healthfulness or unhealthfulness of a locality. He has gathered as much of such knowledge as possible in regard to the salubrity of the Eastern Shore. Reports from a considerable number of local health officers, physicians

and correspondents show that, whatever may have been the condition of this section of the State, as regards malarial and other diseases, in former years, it is now exceptionally healthy—in fact it is more exempt from disease than any other district in the State of equal area and population. This is especially true in respect to malarial fevers and pulmonary consumption.

The facts which have been obtained indicate that malarial diseases have greatly diminished on the Peninsula in the past ten or fifteen years, and that, exclusive of small areas affected by local conditions, the proportion of uncomplicated malarial fevers to all other cases of disease is not more than *two per cent.* This great reduction in the number of cases has been secured through a better knowledge of how to avoid the causes of disease, rather from any system of medication ; and it is hoped that, by further application of well-known sanitary laws, intermittent and remittent fevers will be banished from the list of prevailing diseases on the Eastern Shore of Maryland.

The Dispensing of Digitalin.

The Paris correspondent of the *Chemist and Druggist* reports on a discussion on digitalin recently held at a meeting of the Paris Société de Pharmacie, as follows:

M. Petit called attention to the vexed question of digitalin, or rather digitalins. As regards crystallized digitalin there is no difficulty when it is prescribed as such. The dose is one-tenth of a milligramme, and it makes but little difference whether Nativelle's or the German crystalline principle (by them called "digitoxin") or any other be employed. But the trouble is with amorphous digitalins. According to law it is this sort that should be dispensed when no remark is make by the prescriber, and the preparations offered in the market as amorphous digitalins are exceedingly variable in strength. Some, such as the Codex article, which are completely soluble in chloroform, are considered by good authorities nearly equal to the crystallized principle; but others must be much weaker, since they are taken in 1-mg. doses, which would be sure death with the pure product. As to the German sorts offered, they are of all varieties and prices, from less than 1 franc or 3 francs a gramme, not to speak of the so-called digitoxin. In consequence of this great variation, M. Petit moved that a commission be appointed on the question, so as to arrive at some agreement in regard to uniform practice in dispensing digitalin. The motion was unanimously concurred in, and MM. Petit, Marty, Wurtz and Delpech appointed a committee to consider the matter and report.—*American Druggist*, April, 1890.

Curability of Hydrophobia.

In the data collected by Dr. Lucas Benham, and published in the *Lancet*, March 1, 8 and 15, 1890, there is a fair amount of the evidence that hydrophobia may be successfully treated. This evidence does not, however, afford much satisfaction, inasmuch as the cases on which most reliance has been placed—those, namely, where bleeding and salivation have been freely employed—are derived from the records of the early part of this century. In many of the narratives supplied by Dr. Benham there is a candid confession respecting the doubtfully rabid condition of the animal that inflicted the bite. In others the symptoms seem to be exaggerated. Dr. Benham's candor and impartiality are to be commended.

Pitjecor.

Pitjecor is the name given by Dr. Luigi Casati to a preparation of cod-liver oil and catramin. It is free from fat, but not emulsified. It is said to be of special value in chronic affections of the lungs, particularly in tuberculosis. Catramin (a preparation made from pix liquida) is said to act directly upon the tubercle bacillus. The results obtained by Dr. Casati with the preparation were most encouraging.—*Wiener med. Presse*, Feb, 23, 1890.

Hydrophobia in Paris. Pasteur Institute Statistics.

The *Bulletin Médical*, March 26, 1890, reports that in the year 1889 there were treated at the Pasteur Institute 236 persons from the Department of the Seine (Paris) alone, supposed to have been bitten by rabid dogs. Of these persons three died after treatment. During the same period three other persons died of hydrophobia in Paris.

NEWS.

—Dr. Robert Coltman, of Chinanfu, China, on April 1, 1890, assumed charge of the Teng Chow Fu Hospital.

—The Board of Charities and Correction, of Philadelphia, on April 16, elected Dr. J. M. Barton, surgeon to the Philadelphia Hospital in place of Dr. Henry R. Wharton, resigned; and Dr. C. Jay Seltzer was elected laryngologist.

—The Medical Society of the Missouri Valley held its regular quarterly meeting in St. Joseph, March 20 and 22. The Society was organized over a year ago at Council Bluffs, Ia., and now has a membership of over two hundred.

—A professor in the University of Klausenburg claims to have compounded a solution which completely neutralizes the poison introduced into the system by the bite of a mad dog. This solution consists of chlorine water, salt brine, sulphurous acid, permanganate of potassium and eucalyptus oil.

—The sixty-ninth annual commencement of the Philadelphia College of Pharmacy took place April 17. The valedictory address was delivered by Professor Joseph P. Remington, Ph. M. Among the graduates were five women, two of whom did not receive their diplomas, being under twenty-one years of age.

—It is reported that two families, consisting of sixteen persons, were poisoned last week in Franklin County, Arkansas, by eating wild turkey, and twelve of them, up to the last accounts, were not expected to survive. It is believed that shortly before being shot the turkey ate some strychnine bait which had been set for wolves.

—A dairyman of Chester County, Pa., has complained to the health authorities of Philadelphia about the filthy condition in which milk cans were sent back to the dairies. He stated that very frequently these cans are allowed to stand for weeks with milk decaying in them and breeding impurities which decomposed animal matter is subject to.

—Professor Ulysse Trélat, the distinguished French surgeon, died March 28. For many years past Dr. Trélat had been Professor of Clinical Surgery in the Academy of Medicine, of Paris. He was sixty-two years of age. He took his degree in 1854. Military honors were rendered the deceased at his funeral and several orations were pronounced over his grave.

—The New York Pasteur Institute was opened on February 18, and from that date to March 31 thirty people applied for relief. Of these 9 were treated, and are at present in good health. In 3 cases hydrophobia was assumed to exist from the results of inoculation of other animals with the spinal cord of the rabid dogs. Four of the patients were from New York City, 3 from Long Island, and 1 each from Maryland and Arkansas.

—The following medical commencements have been held recently:—Fort Wayne Medical College, March 11, 7 graduates; Beaumont Medical College, March 20, 23 graduates; Central College of Physicians and Surgeons, Indiana, 8 graduates; Medical College of Indiana, 28 graduates; Western Reserve University, Cleveland, O., March 5, 30 graduates; Atlantic Medical College, 51 graduates; Southern Medical College, March 5, 33 graduates.

—The National Academy of Sciences, in Washington, on April 18 elected as members of the Academy, George L. Goodale, Professor of Botany in Harvard College; Russell H. Chittenden, Professor of Chemistry in Yale College; Richard M. Smith, Professor of Political Economy in Columbia College, New York, and General Thomas L. Casey, Chief of Engineers, U. S. A. One vacancy remains unfilled, it having been found impossible to agree upon the persons most worthy to be honored.

—The druggists of Baltimore have been much exercised over the provisions of the new Liquor License law. A largely attended meeting was held April 17, to discuss the new law. The law was characterized as absurd, and it was stated that if it were enforced literally, the druggist would be legislated out of business. A committee was appointed to consult with the State's Attorney, and get a written statement of the construction the druggists are to put upon the law, and the extent to which their business as now conducted will be affected by it.

—Twenty-two physicians who were employed on the summer vaccinating corps by the Brooklyn Health Commissioner, and who have not been paid for their services, have employed lawyers and had claims filed preparatory to suing the city. They have not been paid because the Civil Service Commission said they were irregularly employed. Commissioner Griffin employed them in an emergency, believing that he had full power to do so. There is no question as to the performance of the work charged for. The amount of the claim in each case is $120.

Clinical Lectures.

INFLUENZA AND PERIMETRITIS.—SYMPTOMS OF PREGNANCY.—BEGINNING OF MENOPAUSE.—STERILITY FROM A MISCARRIAGE.

BY DANIEL T. NELSON, A. M., M. D.,

PROFESSOR OF CLINICAL GYNECOLOGY IN RUSH MEDICAL COLLEGE, CHICAGO, ILLINOIS.

Gentlemen: We have before us to-day four cases, characteristic of what you are likely to find in your offices after you have been practicing medicine for some time. The first thing you do is to find out the cause and nature of the trouble in each case; its extent, what to do, and what not to do; and the latter is sometimes most important as regards treatment, in so far as the relation of other diseases to pelvic disorders are concerned.

Influenza and Perimetritis.

Here, for instance, is a young woman who came to the clinic for the first time four years ago. She was 18 years old at puberty, and is now 28 years old and of Swedish parentage. She complains of pain in the limbs, pain in passing water, and a leucorrhœal discharge, which has increased of late; her bowels are irregular; her appetite poor; she is very nervous; she sometimes sleeps well, sometimes poorly; her menses are irregular, occurring sometimes as often as every two weeks, and are small in quantity and light in color; she has a good deal of pain at the time of menstruation. She suffers from abundant leucorrhœal discharge at present, but, she says, the discharge is usually not very large in amount, and is not constantly present.

She has been troubled also with influenza for about two weeks, having pains all over her body. We do not know what her condition was exactly at the time of the attack,

but there is no doubt but that she had the influenza. In this prevailing epidemic of influenza some patients are suffering from diarrhœa and stomach disturbance; others from constipation, loss of appetite, chills and fever, with slight alimentary disturbance; and still others from pains of a neuralgic character in the bones, muscles and limbs—with a stiffness as though they were suffering from muscular rheumatism, etc. It is not our purpose to deal so much with her last illness as the other troubles of which she complains.

A pelvic examination has been made, and no local treatment resorted to. Why? What is the condition of things found? Increased tenderness about the uterus, left perimetritis, the left ovary and tube being involved in inflammation. On making further examination with the speculum, we find a considerable leuchorrhœal discharge in the vagina. There is tenderness on the right side of the abdomen, but it is chiefly confined to the left.

What shall be done with this type of case so far as the pelvic disease is concerned? For the present we should continue to improve her general health as much as possible. In a single word, do not give much attention to the local disorders in the pelvis so long as there is a general or constitutional disease which is making considerable disturbance; so long as there is an increased temperature, considerable pain in various parts of the body, or chills and fever. The simplest local treatment has therefore been prescribed for her—hot water douches, containing borax, or some simple astringent or antiseptic. Borax, however, is likely to do as much good and as little harm as anything that can be used. The hot douches are given at night; after which she can go directly to bed and not expose herself to the changes of temperature which might aggravate the local disease. She should not expose herself after the use of these local baths. In taking any hot bath great care is required afterwards that there shall not be some acute disturbance set up by the process which we call "taking cold." She is directed to have hot applications across the abdomen if there be considerable pain. Later, stimulating applications will be of advantage, such as tincture of iodine, croton oil, cantharides, etc. If she still needs further treatment, it shall be discussed at some future time. When you have an acute disorder of a general character, such as influenza, typhoid fever, pneumonia or other acute disease, it is a good rule to let the local disease go until the general affection has subsided or nearly so.

Again, acute diseases are likely to leave an existing chronic one worse for a time. If she had been vomiting, and having diarrhœa. and if there had been considerable disturbance in the alimentary canal, the mechanical effect of the vomiting and diarrhœa in disturbing the viscera would aggravate the pelvic disease if there were no other reason for it.

Symptoms of Pregnancy.

The next patient I bring before you was 17 years old at puberty, and is now 29 years old; she is of German parentage, has been married five months and has had no miscarriage. Her present illness began four years ago. She was in the Cook County Hospital a year ago, and remained there for three months. She has headache in the morning, at about ten o'clock, which continues for several hours, and then relief comes. It comes on again in the evening at nine o'clock. She feels sick at the stomach before breakfast, and vomits. She suffers from pain in the back, chest and stomach. Her appetite is fair; she does not sleep well; she has burning pains during urination; her urine is of a darker, yellow color than it ordinarily is. While in the County Hospital she had an operation performed upon the perineum and cervix, and since that time she has been much better than before the operation, and the operation certainly was satisfactory in its results, inasmuch as both the cervix and perineum look as though they are in a normal condition. She had a child some four years ago. Her bowels are constipated, and she is obliged to be constantly using injections, or some other means, to move them; she breathes rapidly, especially after exertion, as in climbing stairs; her pulse is 100, and somewhat nervous in character. Her menses stopped eight weeks ago.

Local examination shows the uterus to be slightly enlarged, but not sufficiently so to make a positive diagnosis of pregnancy. Examination with speculum gives suspicious evidence of pregnancy, viz., a blue congested condition of the cervix. While that frequently accompanies pregnancy, it is not by any means a positive proof of it. If you have an arterial or pinkish congestion you may readily be suspicious of pregnancy. If

it is a blue or venous congestion, while it may belong to pregnancy, it may be due to other conditions, one being simply stasis, and the other a greater amount of activity, and the coloration may not be marked in some cases as in others. A fibroid tumor will produce the same venous congestion. If you know there is no tumor present and the venous congestion comes on, and it is near the menstrual period, menstruation will give you venous rather than arterial congestion. There is such a commingling of colors in pregnancy and in the approach of menstruation that you cannot always be sure whether it is the menses approaching, or whether it is pregnancy that has already commenced. In a case like this you may be reasonably certain that it is pregnancy.

On examining the breasts, we see the same evidence of congestive activity. We find them somewhat enlarged, yet they are not as large and as sensitive with increased glandular activity as is found in some cases. The sebaceous glands in the areolæ about the nipples are considerably enlarged. There seems, also, to be an unusual activity going on in the pelvic viscera. We find that the arteries are larger and are pulsating with greater force than in a normal condition of the pelvis, without pregnancy; though this of course will occur in the pelvic inflammations, in malignant diseases, fibroid tumors, and many other forms of pelvic disease. The arterial congestion to my mind is of more importance as rendering pregnancy suspicious than almost any other symptom. While the uterus is enlarged, it has not changed its form so materially as it does sometimes to make a positive diagnosis of pregnancy from its shape. With the finger passed behind the cervix, it seems to have its ordinary contour as far as the vagina can be crowded backward. Carrying the finger upward, as you go forward, there is a greater rapidity in the elevation of the walls of the uterus than usual. In other words, there seems to be an enlargement on one side (the anterior). It is not a flexion, because if so, both sides would be parallel. The uterus keeps its contour, it does not run up as rapidly as in flexion. We have the same appearance in front in the anteflexed uterus as compared with the pregnant uterus, with the ovum upon the anterior wall. If it were on the posterior wall, then you would have a reversion of this nodular appearance over the enlarged tumor-like projection. If the ovum is attached in other regions you may not get it as marked. The ovum here is implanted directly in front. I do not find the enlargement as prominent in her case as in many cases. This blue discoloration may extend also to the vagina, to the whole vulva, and to the region about the urinary meatus, and, as a rule, is much more prominent in women who have borne several children than in those that have not; or, in other words, in those who have varicose veins. Several authorities have noticed that this blue congestion about the genitals is indicative and suspicious of pregnancy, but I think that the arterial congestion is more significant than the venous congestion.

Of course, I may say in passing, that we have passed no sound into the uterus in this patient supposed to be pregnant. We have given her laxatives and told her to return from time to time that we might watch her. We advised her also to drink hot water to facilitate passing the urine freely, making it lighter in color, and therefore less irritating.

Here is perhaps an explanation of the teasing bladder: the congested uterus presses upon the bladder, and mechanically disturbs it; and perhaps not alone mechanically, for a disturbance is going on in all the pelvic organs, and this irritation or disturbance of the bladder is one of the common symptoms of the commencement of pregnancy. Under such circumstances it is best to examine the urine and see whether there is disease of the kidney, whether there is something wrong with the interior of the bladder that is causing the cystic disorder, or, what is more likely, if there is something in the uterus and adjacent organs which is teasing the bladder.

This condition demands but very little treatment in so far as the discomforts of the bladder are concerned.

For the neuralgia returning periodically at about the same time morning and evening, I would give quinine in full doses (15 to 20 grs. in twenty-four hours, in divided doses), given in the intervals of the pain, and during the pain I would give antifebrin in five-grain doses every two to three hours, for immediate relief. When there are indications for quinine, I do not hesitate to give it in full doses during pregnancy, unless it disturbs the stomach.

Beginning of Menopause.

Let me now read the history of our next patient, an elderly woman sitting on my

right, as illustrating the venous congestion that I have been talking about in the other case, though in a different way.

Mrs. J., 16 years old at puberty, now 49, of Irish birth, married 30 years, has had ten children, the oldest being 28 years of age, and youngest ten years. She had one miscarriage, eighteen years ago, occurring at the third month of pregnancy. You notice that she had her last child ten years ago, being eight years after the miscarriage, so that the bad effects, if there were any, from the miscarriage are likely to have been removed by her subsequent pregnancy. She did not have enough trouble from the miscarriage to produce sterility.

She complains of a burning pain in the womb. There is flatulency or bloating of the abdomen. She cannot sleep on account of pain in the top of the head. She has pain also in the neck and back. You notice that the complaints of patients suffering from uterine disorders of one type or another, are often accompanied by a pain in the top of the head.

The patient feels hot, never cold. Many complain of a cold spot on the top of the head or under the shoulder blade, where there is always pain. This patient, also, has a burning pain in passing water, and pain in the small of the back. Her feet swell; she is very nervous; she sleeps poorly, but her appetite is fair. She has not had her monthly sickness for four months. She has a thick, white leucorrhœal discharge, large in amount, but it has not been constant recently.

Now, what is this case? Is it one of pregnancy like the other, or not? Is the menopause approaching? Let us examine the pelvis and see what we find there. The cervix and perineum are lacerated, and the vagina is very flabby. You are not surprised at this condition of things when you know that she has borne ten children. Her largest child at birth weighed 14 pounds. Is it strange that she has a large vagina, a large vulva, a torn cervix and a lacerated perineum? That she has not suffered more than she has is strange. What do we find besides a lacerated perineum and cervix? On examination we find that both of these lacerations have fairly well healed, and it is not likely that she will need an operation to restore the parts to their normal condition.

The uterus seems to be in its place, and is growing smaller and lighter. It is not as heavy as we would expect to find it in a woman who has borne so many children. The mouth of the womb is flabby; in other words, the uterus is getting smaller, the cervix is getting thinner, the walls of the uterus are getting thinner as a result of senile atrophy. If this goes on we shall have a diminution in the menstrual flow. Some months she flows more than others. This may be due to the fact that there is not much contractile power in the muscles of the uterus so as to hold the blood, and as a result the blood-vessels are open and blood escapes rapidly from the open channels.

As to the question of pregnancy, I did not pass a sound into the uterus. I did not think it were wise to do so, though I had little suspicion of pregnancy; still the color of the two cervices, the one in the woman I told you was pregnant, and in this patient, is almost identical. The venous congestion makes the two cases almost alike, yet one does not indicate pregnancy and the other does. The fact that she has borne so many children is the reason of this venous congestion. There is an enlargement of the venous trunks in the pelvis around the uterus and in all the pelvic viscera. The patient is troubled with varicose veins in the left leg extending up the thigh into the pelvis, which probably accounts for the venous discoloration, which is so marked.

I fully believe the menopause is approaching. The irregularity of the menses is indicative of it. They have been irregular for a year. That is the ordinary way in which the menses stop: first, by a slow diminution, then becoming irregular and finally ceasing altogether.

Remember a word of caution with reference to the return of the menstrual periods. If, after they have stopped for two, three or six months, they should return with increasing severity and with a larger quantity than usual, and especially if along with the increased quantity you have an offensive odor, you should make an examination at once for malignant disease. If they simply stop for a time and return in their ordinary way, and there is no more offensive odor than formerly, it is a symptom of the menopause. When the menses stop for a time, then return again, especially if there is any odor or considerable increase in the leucorrhœal discharge, make an examination at once so as to find out whether there is malignant disease; for if there is you cannot treat it too soon. If there is to be an operation it should be done at once, as soon as the diagnosis is made.

With this case we believe we have the menopause approaching, from the lessened weight of the uterus, from the diminished menstrual flow and from the irregularity of the menstrual flow; and that the congestion is simply the venous congestion which belongs to the varicose veins in the pelvis and below, not to pregnancy, as in the other case.

Sterility from a Miscarriage.

I will now say a few words with reference to the next patient. She is of German birth, was 14 years old at puberty, and is now 26 years old. She has been married eight years, but has not borne any children; she had one miscarriage seven years ago. For the past week she has been suffering more pain in the back and head than formerly; she also suffers from nausea and vomiting each day after meals. She has been also recently complaining of diarrhœa; her appetite is poor; she complains of frequency of micturition, and has considerable pain when passing urine. Her menses are regular, but she suffers pain during the periods, and flows too much; she has a small amount of leucorrhœal discharge, but this is not constantly present; the cervix slightly lacerated; there is right perimetritis, and the left ovary and Fallopian tube are involved in the process of inflammation. She has been led to come here on account of sterility. She has been married eight years according to the history, and had a miscarriage soon after marriage. Now she suffers pain at the time of sexual intercourse; it makes her feel sick afterwards. She feels quite uncomfortable, and especially so of late. She wants treatment so that she may have children.

Why is she sterile? What condition of things is there in the pelvis to produce sterility? Surely not the lacerated cervix, for that is not sufficiently extensive to produce that. How about the perimetritis—the inflammation that is evidently about the left ovary and tube, and also affecting the tube on the right side chiefly, though the left seems to be involved in the inflammation? There is little doubt in my mind that the sterility in this case is due to the condition of the Fallopian tubes.

While we have learned little as to the cause of the miscarriage, or what accompanied that unfortunate occurrence seven years ago, I believe that if we reason in this wise we will not be far from the truth: That there was at that time a septic infection or inflammation climbing up from the lacerated cervix to the uterus, and then onward into the right Fallopian tube, giving the tenderness about the ovary, and giving her a reason for the pain of which she complains during sexual intercourse. Whether there is also sufficient inflammation in the Fallopian tube on the left side to produce sterility I am not able to say, but I suspect it. The cervix is not in a very unhealthy condition, neither is the uterus. She has very little leucorrhœal discharge from the cervix, so that I believe that it is disease of the ovary and tube on the right side and the tube on the left side that has produced this sterility, and that these diseases came from septic infection, dating back to the miscarriage which occurred seven years ago.

How much can we promise her as regards the certainty of cure so far as the sterility is concerned? That, I believe, will depend largely on the success in removing the inflammation in these deep-seated parts. How shall we do it? Can we do it by galvanism? It would certainly seem from experience in many cases now that galvanism would promise as much as anything that we have at our command. By electricity applied to the interior of the uterus you may directly affect the tube and ovary; but with a comparatively healthy uterus and cervix and a healthy vagina, it does not look as though you will accomplish very much good by other local treatment applied to these organs. External applications of a stimulating character may be of some advantage; but I believe in her case that electricity is likely to be more advantageous and beneficial than any other remedy that can be applied. The galvanic current should be employed in such a manner as not to produce much pain, and that of course will depend entirely upon your experience with it. The proper strength of current necessary will depend upon your experience with this particular case. Five or even ten or more milliampères may be necessary. The electricity may be employed once a week. Twice a week is the rule, and not oftener than three times a week, the current being applied five minutes at first, then ten, fifteen, or even twenty minutes later. But be sure to use a mild current at first that shall not produce much pain. Attention should be paid to the condition of the bowels, to the appetite, and gases in the alimentary canal. Mercury in small doses—one grain—three times a day, may be given, with some simple anodyne or

astringent along with it, if necessary. Powdered salol, or the pills of salol, five grains each, may be given three or four times a day; corrosive chloride in pills of one-hundredth of a grain each may also be administered if the gases are in the stomach and returning from that region. In a word, attend to her general health, at the same time look as best you can after the local health. Promise her the best attention and skill you can command. Be careful not to promise her that you will effect a cure in a month or two, so that she will become pregnant; for sterility is one of the diseases the cure of which is exceedingly uncertain.

In a case like this, where there is a possibility that both tubes are diseased and one ovary involved, be careful about promising to cure the sterility. Of course an operation for a permanent cure of her ailments—diarrhœa, backache, her stomach disturbance, headache, etc., by the removal of the ovaries and tubes is not to be thought of until you have given up all hope of relieving the local disease and carrying out her wish of being a mother. It may be necessary eventually to remove the ovaries or tubes, but do not think of it at present. If you can, by your skill, get the patient so well that she may become pregnant and bear children, you are likely by the wonderful changes that take place during pregnancy to have the local diseases we have pointed out in the condition of the tubes and ovaries, one or both, as the case may be, completely and satisfactorily removed by the processes attending gestation.

There is this caution: Suppose you had succeeded in having her recover sufficiently to become pregnant, and you are so fortunate or unfortunate as to attend her at confinement, remember what you know of her; that she probably had septic infection years ago; that there are likely to be still cysts or pockets in which the virus, bacilli, or infecting germs are still lodged, and which, in the processes which attend parturition, they are liable to be let loose again in the tissues. Remember, I say, her previous history and watch her with greater care, that she may not get subsequent septic infection. You may, with care, protect her from being infected from the outside. As regards infection from herself with this miscarriage, she may become infected by the remains of the disease that existed six, seven or ten years ago.

Just a word with reference to the painfulness of sexual intercourse: I fully believe, and perhaps I have expressed it once before, that it is our duty to find out whether sexual connection gives great pain or not in these cases. It is just as important for us to determine this as to know with reference to mastication whether the teeth are doing their work easily and without pain; whether or not deglutition produces a great deal of pain. It is not at all inappropriate to make such inquiries, but the information should, of course, be obtained in an appropriate way.

"PUS TUBES."—RHEUMATIC "FLAT-FOOT."—TREATMENT WITH A SILICATE OF SODA DRESSING.—SUB-ACUTE RHEUMATISM WITH MITRAL DISEASE.—DISLOCATION OF THE KIDNEY.[1]

BY MORRIS LONGSTRETH, M. D.,

VISITING PHYSICIAN TO THE PENNSYLVANIA HOSPITAL, ETC.

Pus Tubes.

Gentlemen: I have to-day some specimens to show you, which are of a character and quality which we do not often see, and which explain what is so frequently before you now, and so constantly being spoken of in these days. This stomach is evidently an alcoholic affair, very strongly so. If you will examine into the quality of its mucous membrane you will see the fibroid changes there which are characteristic of the alcoholic action. The kidneys also show alcoholic disease. The heart is hypertrophied upon the left side.

These are all interesting; but here is a specimen to which I wish especially to call your attention. It is the uterus with its appendages. This patient has evidently suffered from the incursions of gonorrhœa, although I have no history to that effect. At any rate she has had a tubal inflammation, and here is the closed up and cystic Fallopian tube, in which all of the active symptoms of inflammation have subsided, and, we might say, a cure has been effected. The tube is hermetically sealed, the ovary surrounded with inflammatory lymph, and containing a blood cyst. Menstruation has

[1] Delivered at the Pennsylvania Hospital.

been going on since the closure of the tube; and as the blood could not escape, it has emptied itself into this cyst. This specimen illustrates what I believe is the end to which all of these inflamed Fallopian tubes would come, if they were let alone. The active inflammation closes the openings of the tube, and lymph and pus are thrown out into the tube and accumulate there. When the tube becomes full, the blood supply is interfered with from the pressure within the tube, the thick product undergoes a mucoid degeneration, and a large cystic tube is produced, larger than it was when the pus was in it. In tubes like this, which have become wholly cystic, and in those in which suppuration is still going on, microscopic examination reveals that they are not pus cavities, as is claimed by some gynecologists, but that they are lined with perfectly healthy mucous membrane, lined in many cases with columnar cells. Therefore, this process is not a true suppuration. Many gynecologists remove these tubes, urging as their reason for so doing that there is great danger that the inflammation will spread from the tube and reach the peritoneum, and there light up an inflammation which will produce certain and speedy death. This would be true were the process in the tube a true suppuration; but it is not, and there is no such danger to be dreaded. Then they claim that the Fallopian tube may attach itself to the ovary and adhere, and the inflammatory process extend to that organ, producing there an abscess with a resultant peritonitis and death. This is true, but it is the rarest thing for such an accident to happen. As a rule, the tube does not become attached to the ovary, but soon closes, and the inflammatory process is retained thus, in the tube itself. In a suppurating tube which is not over-distended, we find the mucous membrane in a luxuriant state of growth. The stage which is shown in this specimen is the one to which all such cases will come if let alone. The records of this hospital for twenty years past do not show any death from the bursting of these suppurating tubes, or from peritonitis arising from this condition.

Rheumatic Flat foot.

I have here a case of chronic rheumatism of a form which is rather unusual, and which is generally passed from the hands of one physician to those of another, and which should go into the hands of the orthopedic surgeon. The physician, as a rule, does not do much good for cases of this nature. In a great many instances we cannot do them any good; but in some we can, and I intend trying it here.

Here is a man, strong and hearty, and who has never had any particular illness. He comes to us now suffering from rheumatism in his feet. He is a worker in salt, and consequently his feet are constantly wet. He is unable to stand upon his feet, and you will notice the peculiar flat appearance of the sole of this foot. What has really happened here, is that, either owing to the prolonged exposure to the damp salt or from a true inflammation, the ligaments of the foot have softened, and, their support being removed, the foot has consequently flattened. The man is suffering with flat-foot. People suffering from such a condition have no spring to their feet, and, in fact, walk upon their heels. What I have tried to do in this case, is to build up the instep by giving it some support. As yet, he is no better than when he was admitted. I have endeavored to build up an artificial instep which will exactly fit his foot. To do this we must secure some soft material, which when placed upon a bandage will harden. This support, which I show you now, was put on yesterday about this hour, and has been allowed to harden and dry, although it is not completely hardened as yet. When I put a measure under this foot it seemed as if the centre of the foot, which should be arched, touched the ground. The instep here, you will notice, is broader than it should be, and, as I press upon it, is quite painful to the man. Pressure upon the sole is also very painful.

The support which I showed you was made by taking half a dozen lengths of bandage, cut to fit the foot, and soaking them in "soluble glass"—the silicate of soda. These are laid lengthwise upon the foot, and in this way an instep is gradually built up for the patient. This is a fair specimen of an arch which can be built up in this way. By varnishing this, to prevent the absorption of moisture, we can have a real good support for the foot. I have had to do with a great many such feet, in which the ordinary remedies will do no good; and it is only by doing this one thing that we secure a rest for the foot, and give to the patient the ability to walk. In making this sole we do not wish it to extend too far in front, nor too far back toward the heel, or

the support will come at the wrong point. Each layer is soaked in the sodium silicate and applied to the sole of the foot, and then the whole is surrounded with bandages; and in this way the pressure is made at the points where it is desirable to support the foot. Later we can have a steel made after this model, which can be placed in the shoe as a constant support. Under this treatment the ligaments regain their tenacity and resume their original condition. I will ask this man to stand up and show you how much he can do in the way of walking. There is a little spring left in the right foot, you will notice; but in the left it is almost entirely gone.

Subacute Rheumatism and Mitral Disease.

Here is a patient who comes to us with some rheumatic trouble, which is not very violent at any point. She has often had attacks before this one, and some of them were very severe. After some of these the patient has noticed a shortness of breath, especially after any considerable exertion. The present attack commenced in her elbow four weeks ago, but later shifted to her wrists and the other elbow. All became swollen, one after another. This was attended with a cough at night, some præcordial pain and shortness of breath. There was also excessive perspiration at night, which she called night-sweats, but which we know to be different from night-sweats, as that term is generally understood. Her bowels are regular; her urine is passed freely, although at times it is irritating and scalding, and darker in color than is normal. She complains of pain in her legs, and there is some swelling here, though not much, only a pitting on pressure. Her tongue was very dry on admission, and there were dry, whistling râles in the anterior upper portions of the chest. She had very little fever on admission. There was a morning rise and an evening rise after this, though the fever was not marked.

In ordinary cases of rheumatism we give the patient ten-grain doses of the salicylate of soda every hour until six doses are given, making a drachm in all. This finishes the medicine for the day. But here the woman was given fifteen grains every fourth hour, in a quantity of water, and her diet was kept low. Under this treatment her tongue became moist, and she defervesced on the following day. Now she has but little pain at any place. Her wrists are normal; as are the other joints. Her breathing is a little stuffy yet, and she has a slight cough. There is a little perspiration noticed at night, but no pain in the chest. The râles are almost all gone. Over the præcordial region, at the apex, the first sound is not clear: but it is now very difficult to hear any murmur, although when she was first admitted it was very marked. There is some excitation of the pulse, which, however, was never very rapid. Respiration has never been hurried; but there has been some depression experienced. Her lips and gums are somewhat dusky; but this is not noticed upon the fingers. She is still on a low diet; and she will be kept free from motion until this trouble is all over.

I brought this case in to speak of it in some of its relations, as suggested by the history. It is a case in which a great many joints are involved, and yet there is no great amount of rheumatism present; and in which after many occurrences of rheumatism, there comes on some cardiac troubles. There has never been any heart trouble before, and never any severe, sharp attack of endo- or peri-carditis, and, still, she has a mitral murmur. There has been enough change in the mitral valve and in the heart itself to produce a disturbance of the circulation. There is always a block in the passage of the blood from the right to the left side, whether there be a narrowing or a regurgitation, so the nature of the lesion of the valve is not necessarily important. The treatment is the same in both cases. The difficulty is increasing in this patient's case; the heart is altering in size. Its cavities are dilating, and its muscular walls are failing. Unless her nutrition is maintained, and she is shielded from fresh attacks of endocarditis, she will rapidly run down.

Dislocation of the Kidney.

Here is a very interesting, we might say mysterious, case. The patient has been in the hospital since December 2, when, being a Polish woman, she was admitted with no history. Her temperature on admission was 104°, and since then has varied, reaching at times 105°. Through an interpreter we have learned that, after lifting a heavy weight during her menstruation, she was seized with a violent pain in the back and lower portion of her abdomen. This was accompanied with difficulty in micturition and in emptying her bowels. Her tongue

was dry, black and tremulous. She had had some purgative treatment before admission, and was then having some diarrhœa. Such a history led us to believe she had typhoid fever. Later, when we succeeded in getting some urine, it was found to contain albumin. Very soon it became quite evident that she was not suffering from typhoid fever. She presented none of the characteristic symptoms of that disease. She lay in bed with her feet drawn up, to relieve the constant pain she felt in her abdomen. The abdomen was scaphoid, and with no signs of peritonitis. Her diarrhœa continued through the fourth week she was in the house. The urine she passed gradually increased in amount. Constipation followed, and the urine again decreased in amount. She now has a sub-normal temperature, which has continued for several days. When I first saw her, I got her out of bed. Her urine was then normal in character. Her bowels have been regular since. Within the last few days, without any treatment, she has commenced to pass an enormous quantity of urine. On the nineteenth of last month she passed 25 ounces; two days later, 32 ounces; two days later, 38 ounces; on the first of this month she passed 34 ounces, and on the following days, 46, 48, and 80 ounces of urine, respectively. In less than twenty-four hours she has passed 110 ounces. At one time 25 ounces of urine were emptied out of the bladder. There has been no uremic symptoms; and yet, where has she been storing up this urine? I bring the case before you as a fresh case. The patient is now in a fair state. I think that at first there was some displacement of the organs in the pelvic region, or, what I have sometimes seen, that the severe strain actually gave rise to a dislocation of the kidney. Such a thing has been known to have occurred. As a result here there has been some damming up of the fluid. We shall make an examination of her pelvic and lumbar regions to see what we can find. We shall try to ascertain the size of her kidney when passing urine and when not. Often a dislocated kidney will twist its ureter, and for the time the urine cannot escape. It is curious that a patient can retain such a large amount of urine, and where it is stored up I cannot say.

The Illinois Board of Health has just issued a new edition of its Report on Medical Education.

COMMUNICATIONS.

A HISTORY OF SPECTACLES.

BY L. WEBSTER FOX, M. D.,

OPHTHALMIC SURGEON TO THE GERMANTOWN HOSPITAL, PHILADELPHIA.

Spectacles are crutches for the eyes, said an old writer on optics; but the date at which the invention of spectacles was brought to the notice of the world is now one of the things which have been "lost in the mists of antiquity."

The late Wendell Phillips, in his lecture on the "Lost Arts," said: "And even spectacles are among the things which were known to the ancients;" but on the tombstone of Salvinus Armatus, a Florentine nobleman, who died in 1317, is inscribed that he was the inventor of spectacles. Whether the ancient Egyptians and Phœnicians possessed the knowledge of the action of lenses is only a matter of conjecture. The art of engraving upon glass was known 2423 years B. C., and it is impossible to recognize certain delicate lines in specimens of engraved glass which date back many centuries before Christ, without the aid of a strong convex lens. It is therefore reasonable to suppose that the artist had an aid to his vision in engraving these delicate lines. At one time glass-blowing was the chief industrial occupation of the inhabitants of Alexandria. Rome excelled in the making of glass, and in many respects this art has never been equaled. Pliny tells us that, for drinking vessels, glass was preferred to gold and silver. If the art of making glass had reached such a degree of perfection, why should not spectacles have been also made and used?

History also mentions that Nero (A. D. 68) used to view the games in the theatre from the top of the Procenium, and in the amphitheatre, through a concave glass suspended in front of him, because he was exceedingly near-sighted. Whether or not the ancients had spectacles we do not know; but it is reasonable to suppose that they had at least aids to assist their vision in the exquisite engraving found upon gems and jewels.

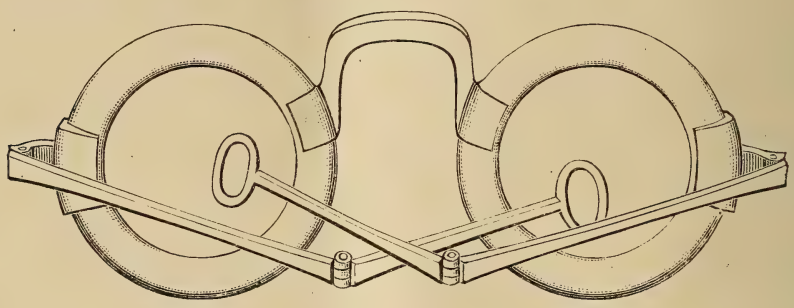
Our first positive knowledge of spectacles is gathered from the writings of Roger Bacon, who died in 1292. Bacon says: "This instrument (a plano-convex glass or large segment of a sphere) is useful to old men

and to those that have weak eyes; for they may see the smallest letters sufficiently magnified." Alexander de Spina, who died in 1313, had a pair of spectacles made for himself by an optician who had the secret of their invention. De Spina was so much pleased with them that he made the invention public. M. Spoon fixes the date of the invention between 1280 and 1311. In a manuscript written in 1299 by Pissazzo, the author says: "I find myself so pressed by age that I can neither read nor write without those glasses they call spectacles, lately invented, to the great advantage of poor old men when their sight grows weak." Friar Jordan, who died in Pisa in 1311, says in one of his sermons, which was published in 1305, "that it is not twenty years since the art of making spectacles was found out, and is indeed one of the best and most necessary inventions in the world."

Granting that spectacles were invented about 1292, it was not known until the year 1600 why certain individuals required convex and others concave glasses.

Kepler, who demonstrated in what manner the rays of light were refracted through the humors of the eye and formed a distinct picture upon the retina, also showed how the images of objects became confused and how concave glasses rendered such images clear. He further explained why it is that the brain receives an erect impression, although the image of the object is inverted upon the retina. After the application of convex and concave glasses for visual defects, the next peculiar discovery was made by Sir David Brewster, who upon testing his vision with a Porterfield optometer (about 1758) found that he could see vertical lines at a distance of ten inches, while horizontal lines were visible to him only at a distance of seven inches.

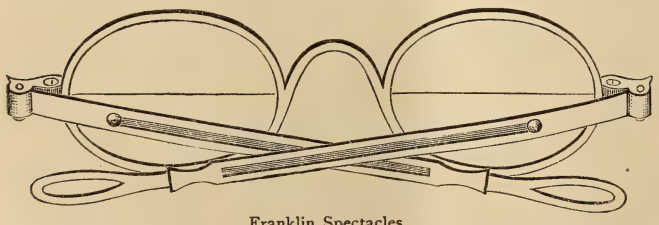
FIG. 1.



Ancient Spectacles.

Benjamin Franklin has been credited with devising a double-focus spectacle—in what year history does not record. Franklin was born in 1706, and being hypermetropic, it is reasonable to suppose that he devised this glass about 1750. These spectacles were split glasses, the upper half to be used for distant vision, and the lower half for reading or near work. The chief objection to wearing this kind of glasses is that they cut off the lower half of the visual field in walking. (Fig. 2.)

FIG. 2.

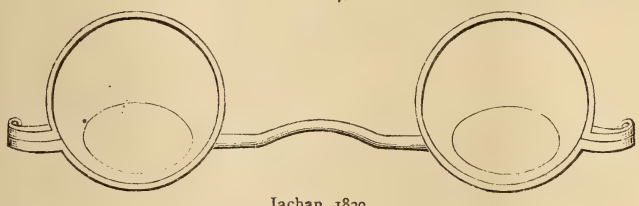


Franklin Spectacles.

Sir David Brewster was the first to discover the astigmatic eye; but the correction of this abnormality of sight was left to Mr. Airy (1825), who found that his left eye had very defective vision, so that he was unable to read with it, while the appearance of a candle-flame looked at with his left eye was not circular—as when seen with his right eye, which was also defective for distant vision—but was shaped like an ellipse, with its long diameter inclined at about 35°. The concave glass which rendered vision distinct for the right eye partly corrected the defect in the left. He concluded that the curvature of the

cornea was greater in one diameter than the other. He found, too, by drawing on paper two lines crossing each other at right angles that at a certain distance from the crossing point one line was distinct while the other was indistinct. He also found that, by bringing the paper nearer, the invisible line became clear and the formerly clear line became indistinct. From these phenomena he concluded that the refraction of one plane of his eye was different from that of the other, and, consequently spherical lenses would not benefit him. His object was then to make a glass which should refract rays more powerfully in one plane than in another plane at right angles to it. He therefore had a lens constructed which was doubly concave, one of the surfaces being spherically concave, and the other cylindrically concave, and of such a curvature as to bring to the same point the vertical and horizontal lines. An optician by the name of Fuller, at Ipswich,

FIG. 4.



Jachan, 1839.

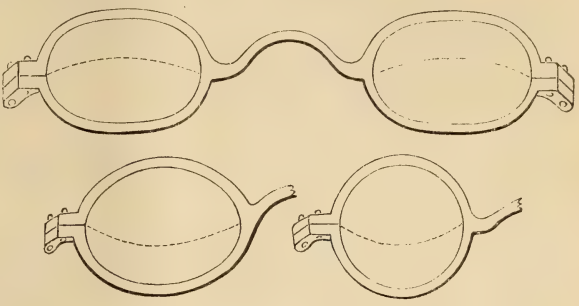
made this glass, which gave Mr. Airy useful vision in his left eye.

An improvement on the Franklin glass was made by Schnaitman, of Philadelphia, who, in 1836, was granted a patent on bifocals, which were the first ground bifocals made in this country. (Fig. 3.) The upper half was used for distant vision, the lower half for near work.

C. H. L. Jachan, of New York, in 1839, was granted a patent of a glass for spectacles, "by leaving a small, circular, clear space opposite the pupil of the eyes, to be surrounded by a ground portion, extending over the remainder of the surface so adjusted as to leave a larger proportion thereof above the eye, and in the case of concave or convex glasses that the centre of convexity or concavity shall coincide with the centre of said clear, circular space. I also claim," he says, "in combination therewith the location of the bridge and the hinges and bows to adjust the clear space to the pupil of the eye all in the manner and for the purpose above described." (Fig. 4.)

Hotchkiss and Norton, on April 17, 1849,

FIG. 3.



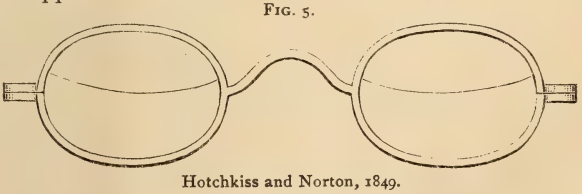
Schnaitman, 1836.

were granted a patent for a bifocal which was exactly like the bifocal glasses devised by Schnaitman in 1836, as show in Fig. 5, and which was no improvement over the spectacles made thirteen years before.

Samuel Gregg, of Boston, in November, 1866, was granted a patent on bifocal spectacles based on the following claims: "constructing glasses of spectacles where two distinct lenses or *segments* of lenses are contained in one glass adapted for seeing near and distant objects in such a manner that the upper edge of the convex lens adapted for seeing near objects shall be concentric with the upper edge of the lens adapted for seeing distant objects for the purpose of enlarging the field of vision." (Fig. 6.)

Edmondson, in 1867, followed with a

FIG. 5.



Hotchkiss and Norton, 1849.

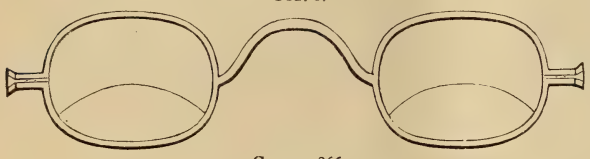
more complex bifocal spectacle. The following is his description of it:

"Fig. 7a is a perspective view; Fig. 7b is a section on the line x x of Fig. 7a.

"Each lens consists of two pieces, of different magnifying powers, and set in different planes. The line of division between

the two is the horizontal mid-section; the upper portion is of greater focal distance for viewing more distant objects. The plane of the upper portion is at right angles to that of the bows, and at about the same angle to the axis of the eyes when adjusted horizontally. The plane of the lower halves is inclined to the former so as to be about at right angles to the axis of the eyes when declined in reading, etc.

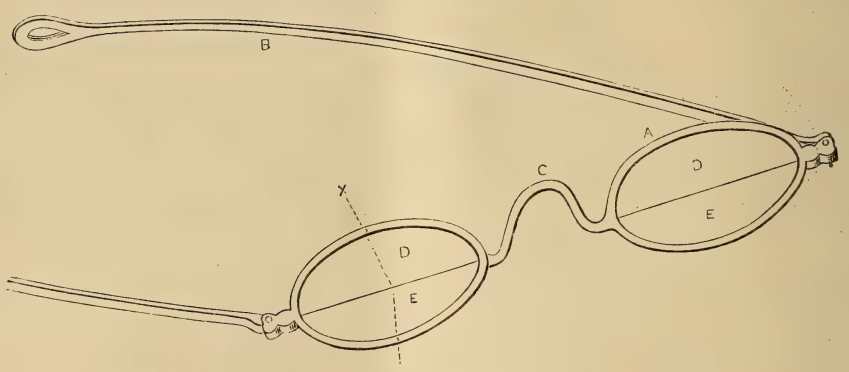
Fig. 6.



Gregg, 1866.

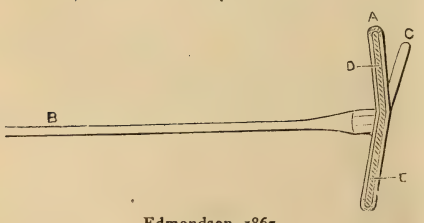
"In the drawings, A A are the bezels, which confine the lenses; B the bows, by which the spectacles are clasped to the head; and C the bridge by which they are supported in position. The lenses in each case consist of two pieces. The upper half, D, is of a longer focal distance than the other, that is, less convex; it is designed for distant objects such as ordinarily seen by a party walking, objects which are assumed to be about the height of the eye and short distances above and below. The lower half, E, is of a more convex character, so as to suit the eye for reading, writing, needlework, etc., for which purpose a stronger power is generally required, as is familiarly instanced in the case of a person reading with spectacles and looking over them at persons or other ordinary objects at a greater distance than the book. It is desired to maintain the proper relative positions of the two portions to the axis of the eyes, and to secure this the upper half is in a plane at right angles to the bows B, so that the portion D meets the requirements of the eye when looking straight forward at the scene, and the portion E is at such an angle with the portion D as will correspond to the ordinary declination of the axis of the eyes in reading, etc. This adjustment of focal length and plane to the varying conditions and requirements is a valuable and hitherto undeveloped feature in spectacles.

Fig. 7a.



Edmondson, 1867.

Fig. 7b.



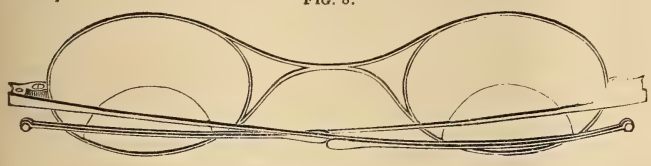
Edmondson, 1867.

"I have heretofore spoken of the invention in reference to the use of convex glasses, in which case the upper portion has the least power, but my improvement is also adapted for glasses for those troubled with myopia, in which case the upper half would be the stronger power, more concave than the lower."

I have in my possession a pair of bifocal spectacles which came from Paris in 1870, in which a *supplemental* lens was cemented on the lower third of the distant glass, and is semicircular in form. This added lens is ground exceedingly thin at its outer and upper periphery, so that in looking through it the juncture between distant and near

glass cannot be noticed by the wearer. How long these spectacles had been in use in France I have not been able to ascertain; but they were not considered a novelty when I purchased them. In fact, these spectacles are of the same style as those which have recently been so much written about and advertised in theatre programmes, as something entirely new and novel. (Fig. 8.)

Fig. 8.



French Spectacles. Before 1870.

Ira S. Doten, in May, 1877, devised and patented spectacles having separate frames from the frames of the spectacles proper, and having such frames on pivots, so that the glasses may be turned to bring the required foci into proper position for use.

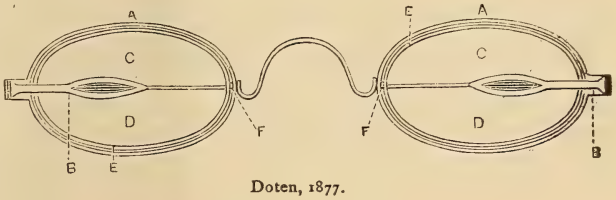
"As shown in Fig. 9, the spectacles are arranged for reading, the section D, having the strongest focus, being down. In this position the upper segment C can be used, if it is desired to look at anything above the wearer, at a distance off, without changing the positions of the foci; but when it is desired to use the spectacles for walking, the segment C must have the lowest position, as the eye naturally looks down in walking; and to attain this end all that is necessary to be done is to revolve the frame E, bringing the section C to the lowest position, when the focus will be the one required for walking.

"By this arrangement all the advantages derived from two pair of spectacles having different foci will be obtained, and the disadvantages arising from the use of spectacles having glasses with sections of different foci held stationary in the frame will be overcome, as by revolving the glasses the proper focus can be brought into position with no change in the place where worn."

Louis Franklin, in this same year, claims an improvement in spectacles, which consists in so constructing the two glasses that the upper one can be removed or folded back out of the way, so as not to obstruct the vision, or it can be folded down over the lower one, so as to form a double thickness and thereby increase its powers for reading.

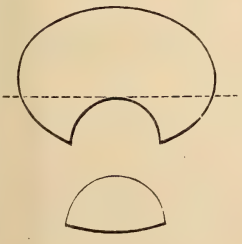
In all spectacles of the bifocal pattern, cylinder glasses were not added up to this date. When it was necessary to use a stronger glass for reading, an "extra front" spectacle was universally given, or else the presbyopic correction was added to distant-vision glasses necessitating two pairs of spectacles. To overcome this inconvenience I suggested to John L. Borsch, the optician, in October, 1883, the practicability of cutting out a segment of the distant glass which had a cylinder glass added, and inserting a sphero-cylinder, which was useful in reading. By such a mechanical contrivance it is obvious that but one pair of glasses was needed for distant and near work. These spectacles, from the manner in which they were made, had their optical centres in the geometrical centres, and in consequence had not the disadvantage of a prismatic effect. (Fig. 10.) One serious objection was raised against these bifocals, and that was that, where it was necessary to give a combination of high power, the curved lines formed by the double refracting surfaces at the juncture of the lenses interfered with vision. In low powers, however, this was not so noticeable. The "curved line objection" was overcome

Fig. 9.



Doten, 1877.

Fig. 10.



Fox, 1883.

Fig. 11.

Fox, 1883.

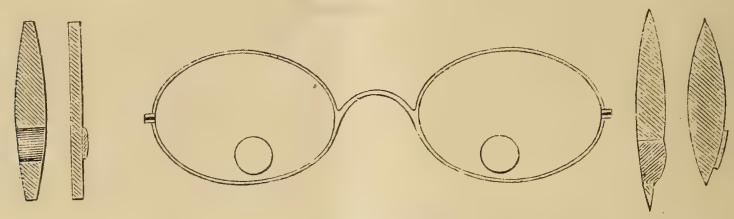
by Borsch, in making an "improved bifocal" in which the segmental lens was cemented upon the long-distance glass, grinding this supplemental lens so thin at its upper and outer periphery as to make an almost invisible line at the juncture of the two glasses. (Fig. 11.)

The only originality to which I lay claim is the adding of the cylinder glass to the sphericals. Gregg devised the cutting out of the *segmental* lens, and the French opticians the cementing on of the *supplemental* lens.

Roberts, in 1884, follows with a revolving spectacle practically the same as devised by Mr. Doten.

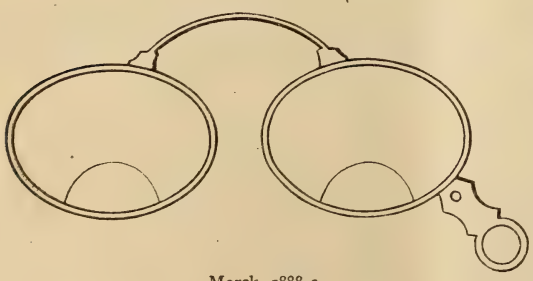
In October, 1884, Dr. B. M. Hanna, of Pittsburgh, received a patent for an improved bifocal lens. Whether or not Dr. Hanna combined cylinder glasses with his spherical glasses I have not ascertained. He, however, claimed only the improvement "to all ordinary forms of lenses, whether double convex, periscopic convex, double concave, periscopic concave, or other form."

Fig. 12.



Hanna, 1884.

Fig. 13.



Morck, 1888–9.

"In constructing," he further says, "such eye-glasses, the short-focus lenses may be cemented on the long-focus lenses, or they may be formed in the original operation of grinding, or by subsequent grinding, or the lens may be bored out and the lenses inserted with cement. I, therefore, do not confine my invention," he says, "to any particular mode of construction, as that will be best determined by the circumstances of individual taste, conditions of use, relative cost, or the fancy of the maker. Likewise the form of the lenses may vary." Dr. Hanna has only one claim to originality, and that is the insertion of the reading glass in the perforation made in the distance glass. (Fig. 12.)

George W. Wells, of Southbridge, Mass., received a patent, June 2, 1885, and claims as new a bifocal with a cemented supplemental lens, consisting of a whole lens of the weaker power required for the upper portion of the completed lens and a half lens applied to the inner face of the whole lens to give the stronger power required in the lower portion of the completed lens.

This bifocal lens is exactly the same model as the one made for me by Mr. Borsch in 1883, and was followed by Morck with a similar one five years later. (Fig. 13.)

August Morck, Jr., was granted a patent in October, 1888, in "reference to certain improvements in spectacles or eye-glasses, and its object is to render more effective such spectacles or eye-glasses as are employed for combined near and far range purposes." Morck was the first to claim by patent, "in combination with spheres, *cylindrical* glasses and prisms." In describing the segmental lens which is cemented upon the long-range glasses, he uses the following language: "Is made to taper to a feather edge along the segmental line, and therefore the lens has its thickest part along the lower edge. This construction obliterates the surface-line to the sight while giving a perfectly defined area for near vision." In April, 1889, Mr. Morck received another patent on a "spectacle lens," in the construction of which he employs "two lenses of different powers of such configurations and relative sizes as to avoid the objection

of the eye resting at the same time on both lenses and the consequent blurred or dizzy effect upon the vision;" and he claims as new "the combination, with a far-vision lens, having its lower edge cut out centrally in semicircular form, of a near-vision lens shaped to fit said central semicircular opening in the far-vision lens and secured therein by suitable adhesive substance substantially as set."

To any one who has followed this article it must be obvious that Morck's first patent had already been anticipated in the glasses in use in Paris in 1870, by me in 1883 and by Dr. Hanna in 1884. His second patent was anticipated by Gregg in 1866 and by me in 1883.

Having now given a history of the development of the "bifocal" lens from Franklin's day to the present writing, I must describe a "trifocal" which was made for me by Messrs. Borsch & Rommel, January 15, 1890. The patient required *sph.* + *1. D.*, for distance; *sph.* + *3. D.*, for (piano) music; and *sph.* + *4.50. D.*, for near work. The occupation of the individual made necessary this kind of glass, which has been worn constantly up to the present with entire satisfaction. (Fig. 14.)

Where it is necessary, concave or convex lenses, with or without cylinders, may be made in like manner.

The base glass is the *sph.* + *3 D.*, the optical centre coinciding with the geometrical centre—understood in optics as the normal centre—and is the glass used for medium vision. The segmental lens may be ground in such a way as to preserve its prismatic effect. In other words this lens has the following equation:—*1.50 D. sph.* on one surface and—*0.50 D. sph.* combined with a prism 3°, base up, which, when cemented upon the *sph. 3. D.*, equals *sph.* + *1. D.*, optical centre coinciding with geometrical centre; being the glass used for long range. The lower, segmental lens equals on one surface *sph. 1.50 D.* on the other surface *sph. 3. D.*, with prism 3° base down; which when cemented to the *sph.* + *3. D.* (base glass) equals *sph.* + *4.50. D.*, reading glass, the optical centre coinciding with the geometrical centre of near vision. If the base glass is of a higher or lower refractive power, the figures of the segmental lenses will vary correspondingly; and it is of great importance that the optical centres coincide with the geometrical centres; which has not been so in the old bifocals and in many as made to-day.

This brief sketch—which makes no pretension to completeness—shows how true it is, that there is nothing new under the sun.

Latest Improved Spectacles.

A CASE OF ANEURISM OF THE ABDOMINAL AORTA.

BY A. HAMILTON DEEKENS, M. D.,

RESIDENT PHYSICIAN AT ST. MARY'S HOSPITAL, PHILADELPHIA.

Aneurisms of the abdominal aorta, though our statistics show a considerable number of cases, are still sufficiently rare to merit a record. The following case, while showing several points of interest, is mainly interesting owing to its doubtful diagnosis, even to the last; when death and a *post-mortem* settled all doubts on the subject.

The history in brief was as follows:

Eliza Campbell, widow, æt. 38, born in Ireland, had one child, which died. She gives the following history. Came to the United States three years ago, after the death of her husband, and has since worked out for a living. The last year of her life before entering the hospital she had worked mostly at washing clothes, and had been a healthy, strong woman all her life, with a good family history. In the early part of last February, while washing, she felt a pain in her back, on the right side, just below the shoulder blades, and thought she had sprained herself in her work. The pain remained constant, but was not sufficiently severe to call for medical skill; and no attention was paid to it, other than to rub on some liniment. In a few weeks—just how many the patient did not remember—she noticed that there was a small lump or swelling on the right of the spine in the position of the painful spot. She mentioned the fact to some of her friends, who thought she was getting some kind of a tumor, and suggested painting it with iodine, which she did, continuing to do so for about two weeks with no diminution in the size of the tumor and no lessening of the pain. She now began to feel that her general health was suffering, and went to St. Mary's Hospital Dispensary for constitutional treatment. While coming there, her principal complaint was of pains and aching in her stomach and back, while mere incidental mention was made of a lump on her back. As the laity in general have a rather hazy idea as to the exact location of the stomach, confining it to a very uncertain area with boundaries at the ensiform cartilage and pubic bones, the Dispensary Physician concluded that her main symptoms emanated from some vague uterine trouble and treated her accordingly. Her condition not improving after a short treatment at the Dispensary, she was advised to enter St. Mary's Hospital and to undergo a thorough examination; which she did, entering April 10, 1889.

Examination at the Hospital showed a large pulsating swelling on the back, situated to the right of spine and about midway between the axilla and the crest of the ilium. The swelling at that time could scarcely be called a tumor, but rather a pulsating projection on one side of the back, with very faintly sloping sides which embraced a large area. On palpation it did not give the expansile pulsation characteristic of aneurisms, but rather the to and fro or throbbing pulsation which is communicated with each heart beat. Another characteristic feature of aneurism, viz., the *bruit*, was absent, except at rare intervals, when a faint sound could be heard. Pressure did not give pain; on the contrary a strong, firmly-applied binder encompassing the whole body was one of her greatest sources of comfort to the woman. She complained about this time of sharp, shooting pains, which she compared to that of an electric battery worked inside of her. When I first attended her, about two months later, the swelling had increased very much in size and attained more the appearance of a tumor, in the commonly accepted designation of the term. The pains were now intense and more of a steady and gnawing character, and she compared them to the sensation of the nibbling of a mouse at her insides. The pains were mostly referred to the umbilical region, radiating down to the right hypochondrium. They were so intense that large doses of morphia, hypodermically, were necessary to quiet her. During the last month she took between five and six grains daily; and even that large amount often did not suffice to ease her sufferings. Her staple treatment was rest, with light diet, principally milk and broth. Her appetite left her entirely. Iodide of potassium was tried, but she refused to retain it. Simple tonics, such as quinine, gentian, etc., were given as long as her stomach would stand them. The bandage before referred to, with alcohol bathings, afforded her the greatest relief.

The *ante-mortem* diagnosis was full of doubt. Some physicians claimed it for an aneurism of uncertain location; others diagnosticated it as an internal tumor or abscess of debatable origin; and up to within a week of her death the advisability of tapping

it was suggested. Some thought it might have originated in the lung, or in the liver, from the hepatic artery. The thoracic aorta was included in these suggestions, also the abdominal aorta just below the diaphragm.

On October 5, 1889, the woman died, and on the following day I made the *post-mortem* in the presence of several physicians; and the true state of affairs was made out. It proved to be a sacculated aneurism of the abdominal aorta, commencing directly above the cœliac axis, and including an inch and a quarter in length of the aorta. It expanded into a sac which filled the greater part of right side of the abdominal cavity, and crowded the right lung into half its usual bulk. It extended two inches to the left of the spine, and below to a level with the crests of the ilia. The adhesions were so extensive and so strong that it was impossible to detach the sac from the surrounding structures. An approximate estimate of its circumference would be between thirty and thirty-five inches. It was firmly adherent to the abdominal walls, peritoneum, liver, intestines, etc. Its interior was nearly filled with organized fibrin, great masses of which I could take out with my hands, and several of which I have kept as specimens. Several of the ribs, posteriorly, had entirely disappeared. Several of the vertebræ were partly eroded, and sharp spiculæ of bone could be broken off them.

Among the symptoms complained of towards the last were a "swelling feeling in the throat," and painful pulsation in the neck on the right side. The woman's mind became visibly affected, and from being a cheerful, happy patient, she became melancholy, crying for hours at a time, thinking that she was going to be taken away from the Hospital; and no persuasions of her attendants had any effect in changing her ideas on the subject.

CONSUMPTION TREATMENT DONT'S.

BY THOMAS J. MAYS, M. D.,

PHILADELPHIA.

Don't prescribe for a chest disease until you are sure of your diagnosis.

Don't have a stereotyped prescription of cod-liver oil, hypophosphites, plenty of exercise, etc., for every case of consumption.

Don't despair of doing some good in every case; and never give a hopeless prognosis to your patient.

Don't overlook the fact that consumption is as amenable to treatment as are other chronic diseases.

Don't neglect details in treating this disease. Your success depends on your ability to control every movement of your patient.

Don't fail to realize that the pulmonary disorder is but the manifestation of a more deeply-seated disease.

Don't forget that in chronic pulmonary disease the digestive organs are of as much importance in treatment as the lungs.

Don't make up your mind to send your patient to Colorado or some other health resort as soon as you discover that he is suffering from consumption; but always bear in mind that, until he is convalescent, such an invalid is best off in a climate to which his body has, by long residence, become adapted; and that the practical results of high altitude treatment are not more favorable than those obtained nearer the sea-level.

Don't fail to perceive that bodily rest is the paramount factor in the treatment of this disease, and that next comes good nutritious food.

Don't let your patient dissipate his strength by walking or by exercising in any way; and always remember that he is on the verge of physiological bankruptcy, and that he must increase his capital stock of vitality by lessening his expenditures and by enlarging his income, or he will become insolvent.

Don't consign him to his room day and night if the weather is pleasant, and if it does not weary him to sit or lie in the open air: care being of course taken to protect him from unfriendly draughts of air.

Don't neglect to have his body well covered with woolen underclothing, which he wears day and night and changes every three or four days.

Don't let him know what the dining table has in store for him, because he always eats best when he is surprised with food.

Don't underestimate the value of the cook. The salvation of your patient is in her hands. She must be dexterous and able to render the food tempting and digestible.

Don't forget that the evening temperature of the patient must be reduced to or below 100° Fahr. before you can expect much permanent improvement.

Don't waste your own and the patient's time by giving quinine, salicylates, thallin, etc., to lower fever when you have such

serviceable antipyretics as antipyrin and phenacetin.

Don't discontinue the antipyrin or the phenacetin after the temperature is reduced, but administer them in smaller doses for the purpose of securing their excellent tonic effects.

Don't confide in antiseptic inhalations as having any influence on the phthisical process, although they are often useful in subduing a troublesome cough, and in allaying a bronchial irritation. Carbolic acid, creasote, and benzoic acid are used for this purpose.

Don't overlook the value of hot poultices applied to the chest during the day.

Don't lose sight of the fact that one grain of quinine, a quarter-grain of opium, one-grain of powdered digitalis leaves, one-sixtieth of a grain of strychnine, one five-hundredth of a grain of atropine, given in a pill four times a day, is a good tonic.

Don't forget that a consumptive who, on account of cough or other causes, cannot sleep at night never gets along well. Nitrous oxide by inhalation during the day and evening, and potassium bromide and codeia at bedtime by the mouth, often secure rest and sleep.

Don't omit to compel the patient to practice pulmonary gymnastics, both by forcing voluntary breathing, and by inhaling oxygen and nitrous oxide from a compressed air apparatus.

Don't overlook the great value of cod-liver oil when it agrees. It is best given pure, with a little lemon juice or vinegar before and after its administration. The hypophosphites must be given when the oil disagrees, or alternated with the latter.

PERISCOPE.

Intravenous Saline Injections in Diabetic Coma.

A striking case was related by Dr. Dickinson at the last meeting of the Clinical Society, and was somewhat encouraging as to the value of intravenous injection of saline fluids in cases of diabetic coma, although, unfortunately, a fatal issue eventually ensued, for after the first injection—of 106 fluid ounces—the patient regained consciousness to a very complete extent. The importance of such a respite may occasionally be very great—for instance, in the case of one who is attacked with diabetic coma without having made his will. It is something to know that by this method the coma can, temporarily at least, be made to pass away. The subsequent course of Dr. Dickinson's case is equally instructive. The patient relapsed into coma, and resort was again had to the procedure which had already proved of service. But this time the amount of saline fluid received into the circulation was actually more than the estimated average total amount of blood in the adult body. In spite of the state of plethora which so heroic a course must have produced, the patient once more regained consciousness. Dr. Dickinson's conclusions, that 100 or even 200 ounces of saline fluid may in such cases be introduced into the circulation with advantage, but that the benefit to be gained thereby can only be temporary, were doubtless justified by the experience in this case. Perhaps the same end might be obtained more rapidly if the injection were preceded by venesection, so as to secure a greater degree of dilution of the blood with a comparatively small amount of the diluent. The practice of saline injections in diabetic coma has, as Dr. S. Mackenzie remarked, been frequently employed, but in no case with permanent good results. Indeed, few patients submitted to this treatment have, as in Dr. Dickinson's case, regained consciousness even for a short time.—*Lancet*, March 8, 1890.

Operation under Hypnotism.

In the *Medical Record*, January 4, 1890, Dr. Edward L. Wood, of Minneapolis, Minn., gives the following interesting story of a very remarkable occurrence. The case occurred in the private practice of Dr. Hugo Toll, of Minneapolis, but came under the personal observation of Dr. Wood. A. S., male, aged seventeen, Scandinavian, entered the hospital September 8, with osteo-myelitis in the upper third of the humerus. There was considerable pain and swelling, some redness, partial immobility of the shoulder and elbow-joints, and three fistular openings, one directly in the axilla, one slightly above the insertion of the deltoid, and the third higher up the arm and more posteriorly situated than the last one. In the three days preceding the operation the patient was hypnotized six times by Dr. Toll, in order to get him under

good control. On the morning of September 9 he was hypnotized in his bed, and then led to the operating-room and caused to lie upon the table. The several fistulæ were then explored, scraped out, and washed out, after which an incision four inches long was made on the outer aspect of the upper third of the arm, to the bone, and an opening three inches long and three-fourths of an inch wide chiselled to the medullary canal with considerable difficulty on account of the osteosclerosis. The work was done under thorough antiseptic precautions. One fistula connected with the incision, and into the other two drainage-tubes were inserted, the recent wound was packed with iodoform gauze, and dressings were applied with great ease, as the patient, while still cataleptic, could turn from side to side, move about, or sit up, as we directed him. At 9.50 A. M. he was led to his bed, and told that at twelve o'clock he could sit up and have something to eat, the nurses, meanwhile, being cautioned not to disturb him. He lay perfectly quiet until that time, and at twelve o'clock, sharp, sat up in bed, stretched his well arm, and said, "Dr. Toll said I could have something to eat at twelve o'clock."

Amputation above the elbow would certainly not have been more painful than this operation, yet the hypnotic condition was preserved through it all, with a loss to the operator of not more than a minute and a half, all told. Dr. Wood has seen several minor operations done with the patient in a cataleptic condition, but he says—and no wonder—that this case was a revelation to him, as he thinks it will be to many of his fellow-practitioners.

Operations on the Prostate.

Dr. W. T. Belfield, 612 Opera House Building, Chicago, is engaged in collecting, for publication, cases of operation upon the prostate, particularly those for the palliation or cure of the so-called prostatic hypertrophy. He requests information concerning cases in which the operations named below, or others designed to secure the same result, have been performed. If already published, a simple reference to the periodical will enable him to secure the information; concerning unpublished cases, he would be thankful for the following items:

Date; age of patient; previous use of catheter; complications (stone, etc.); nature of operation; immediate result; subsequent history; operator (reporter).

The operations about which information is requested are:

1. Supra-pubic prostatectomy.
2. Perineal prostatotomy.
3. Mercier's or Bottini's operation.
4. Incidental removal of portions of prostate in operations for stone, etc.
5. Institution of artificial urinary channel in cases of prostatic obstruction.
6. Operations for malignant or tubercular disease of prostate or bladder.
7. Operations on seminal vesicles.
8. If supra-pubic operation, whether bladder wound was left open or sutured; whether special incision for drainage was made; to what extent bladder was distended or distensible; whether rectal bag was used; whether peritoneum was injured.

The source of information will in every instance be printed.

Nervous Affections in Whooping-Cough.

Dr. Troitski gives, in a Russian journal, a short summary of three cases of whooping-cough accompanied by mental disturbances, difficulty in or loss of speech, and loss of power, or even paralysis, of certain groups of muscles. The first case was that of a little girl two years old, who, during an attack of whooping-cough, complicated by bronchitis, was seized after some paroxysms by distortion of the eyes, blindness and contraction of the arm flexors, quiet delirium and widely-distended pupils, Cheyne-Stokes breathing, diminution of the patellar reflex and of the sense of touch and of pain. At another time she became unconscious, and there were clonic contraction of the facial muscles and staring eyes, the pupils being dilated and not insensitive to light. Soon afterwards a general eclamptic condition with Cheyne-Stokes phenomena came on, the attack lasting for an hour and a half, and giving place to stupor which lasted twelve hours, and during which the child could see, but did not understand, and called things and people by wrong names. These attacks gradually diminished, and in two months she was convalescent. The second case was that of a boy three years and a half old, who had severe headache and difficulty in thinking and speaking during the fourth

and fifth weeks of the whooping-cough, which was complicated by pneumonia. His speech returned after three months, the whooping-cough lasting eight weeks. The hearing was much impaired. The third case was that of a little girl of seven months old, who in the fifth week of her illness had two eclamptic attacks; and in the sixth week impairment of power in the right arm, the deltoid being especially affected. The arm became quite paralyzed after a fit of coughing. Dr. Troitski saw the child again after three months; the paralysis of the arm had disappeared without any treatment, the attacks of coughing having ceased when the arm became powerless. He considers that these conditions were due to disturbance of the circulation, and through that to morbid changes in some part of the brain.—*Lancet*, March 8, 1890.

Preliminary Medical Education.

The *Medical Record*, Feb. 22, 1890, in speaking of the importance of preliminary medical education, says that parents in deciding about the education of a son have to consider not only how to make him the best "medicine-man" and pill distributor, but also how to make him learned, wise, discreet, self-contained, capable of dealing practically with all kinds of people, and also of enjoying a little of the higher intellectual life. The art of medicine depends quite as much on knowing how to meet and handle men as on knowing how to prescribe drugs. The worst physicians are those whose minds from early and immature age have been steadily crammed with technical knowledge, until they see nothing except through ophthalmoscopes, or laryngoscopes, or microscopes, and hear nothing except with the ear to the chest.

Medical success is not dependent on college education nor do we mean to discourage at all those who have not been able to secure it. Some do not need it or are even injured by it. But it is a preliminary education which it is advisable always to try and obtain. And observation shows that there is an increasing desire to obtain it.

Incubation of Measles.

Dr. James A. Myrtle, of Harrogate, writing to the *British Med. Journal*, Feb. 1, 1890, says: "In a young ladies' school with thirty-five resident scholars, a case of measles occurred; the girl was at once removed to a cottage in the rear of the dwelling house, complete isolation secured, a nurse put in charge and all communication cut off. In twelve days the patient and nurse were sent away, and the cottage and everything in it thoroughly disinfected. Exactly fourteen days after this girl showed the disease, a second case occurred; fourteen days after that a third, fourteen days after that a fourth, and fourteen days after that a fifth. Nos. 1, 2, 3 and 5 belonged to different classes, and slept in different rooms; Nos. 1 and 4 were sisters, and slept together; but No. 4 showed the disease eight weeks after her sister. Each case as soon as it declared itself was removed to the hospital. The outbreak in the first instance was supposed to have been caused by infection when away from school, but that is by no means certain, as measles was prevalent in the district. Comment on these clinical records is needless."

Orthin.

Orthin is the designation of another new antipyretic, an orthohydrazin-paraoxybenzoic acid. Prof. Dr. Kobert found by experiments on animals that the muriate salt reduced the fever temperature considerably, and exerted no harmful effect. Dr. Unverricht hereupon employed the preparation in general practice, administering in doses of 4 to 8 grains, but found the effect very unreliable, and accompanied by such unpleasant side-effects that all hope of employing orthin as an antipyretic was abandoned. It was then tried for analgesic properties, and by virtue of its reducing effect in psoriasis, but no advantages could be established over other similar remedies. Both Dr. Kobert and Dr. Unverricht combine in cautioning against further use of orthin.—*Notes on New Remedies*, February, 1890.

Pasteur Institute at Buda-Pesth.

The *Deutsche Medizinal-Zeitung*, March 31, 1890, announces the proposed establishment in Buda-Pesth of a Pasteur institute—as it is convenient to call places where the method of Pasteur for prevention of hydrophobia is systematically practiced. The institute is intended also for the study of protective inoculations in general. The chief officer will be Professor Höyges.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

PRACTICAL POINTS IN THE TREATMENT OF SYPHILIS.

Almost every practitioner of medicine believes that there are at least two diseases which he knows how to treat—intermittent malarial fever and syphilis. To the first, quinine is to be given, and to the second, mercury. It is true that the remedies named are the most important curative agents in these two diseases; but it may surprise the unskilful to learn how much better results can be obtained by adapting the drug to each case, both as regards the time and the way of administering it. Dr. R. W. Taylor, who has had a very large experience in the treatment of syphilis, both in hospital and also in private practice, points out, in a communication to the *Medical News*, December 7, 1889, that most observers have for years been endeavoring so to modify and perfect the administration of mercury in syphilis that all its beneficial effects may be obtained and its deleterious results avoided. The day is long past when intelligent men think it necessary to use mercury to the point of salivation; but there are a large number who still adhere to the practice of "just touching the gums" when they are treating a patient in the early stage of secondary syphilis. Dr. Taylor holds, with many others, that it is vastly better to give it in comparatively small doses and over long periods of time, than to attempt to cure the disease by giving large doses for a few months.

As regards the abortive treatment of syphilis, either by excision or cauterization of the chancre, Dr. Taylor declares it to be an utter failure. He would abandon these operations as prophylactic measures, and employ them only when special conditions rendered them advisable. His opinion on this matter is entitled to considerable weight, for he says he has tried excision extensively over a long period of time, with painstaking attention to details, but he is convinced of its failure, even in cases apparently very suitable to it. Moreover, he is scarcely more partial to the practice advocated by Mr. Jonathan Hutchinson, *i. e.*, the administration of mercury as early as possible in the primary stage—in other words, as soon as the diagnosis of syphilis is made. Dr. Taylor thinks that when given in this stage it tends to render the course of the disease less orderly; very often leaves the existence of syphilis in doubt; does not prevent or lessen the severity of secondary symptoms, and, though it may retard them, it really often renders them more severe.

The best time to administer mercury, according to Dr. Taylor, is when secondary manifestations have appeared, when the newly-formed, young, round, infecting cells are proliferated in vast quantities and are thrown into the general circulation, and by it carried throughout the body. When this has occurred syphilis may be said to be "ripe."

At this time, and not till then, we have something to treat, and it should be treated by interrupted courses of mercury alone at first, and afterwards with iodide of potash; in preference to giving it continuously, or only when symptoms appear. Mercury may be given by the mouth; endermically, by inunctions of soaps or ointments and fumigations; and hypodermically. All these methods of administration have their advantages. In giving it by the mouth, Dr. Taylor prefers the green iodide, and next to it, the tannate. The amount which may be given to each patient varies; but tolerance is very largely dependent upon the condition of the stomach, the pharynx and of the mouth; if these can be kept in perfect order, in the vast majority of cases mercury can be given in such quantities that eradication of syphilis may result. The author is careful to insist upon the importance of keeping the mouth and gastro-intestinal tube in perfect condition, and that all sources of irritation should be prevented or removed. It is well to begin, he says, with a pill or tablet containing one-fourth or one-fifth of a grain of the green iodide of mercury, for persons of ordinary build, but to persons very large and robust, one-third or one-half a grain may be given. This dose may be taken three times a day, and then, if the symptoms do not yield (assuming that there is much constitutional reaction), if the lesions do not show signs of involution, and if the ganglia do not perceptibly subside, a fourth and even a fifth dose may be given within the twenty-four hours. The first course of mercurial treatment should last for at least three months, and, if possible, for four or five. In most cases, at the end of this time, the patient's condition will justify stopping the mercury for from one to three weeks. The next course, Dr. Taylor says, may last from two to five and a-half months, and be followed by freedom from drug taking for four weeks. The mercury may then be resumed and taken for the same length of time. During the second year he is accustomed to combine iodide of potash with the mercury, using either the bichloride or the biniodide. During this second year, all things being favorable, the intervals between the courses may be lengthened, though a full dose of the combined drugs should be given when treatment is used.

Mercurial inunctions are employed by Dr. Taylor for the erythematous and papular eruptions of secondary syphilis, and also for the enlarged lymphatic glands. He gives it as a valuable rule, never to be content with the action of mercurial pills unless there is a decidedly rapid subsidence of the glands. Unusually large, infiltrated syphilitic glands are signs of evil omen, and, as a very general rule, it may be said that they require active, local treatment. Dr. Taylor also employs inunctions in appropriate cases of early and late syphilitic meningeal and cerebral disease, in the headaches of the early and late periods, in the neuralgias of the cranial nerves and in syphilitic neuralgias in general.

In giving mercury by hypodermic injection, he prefers a solution of the bichloride in water. Treatment should be begun with a solution containing one-twelfth of a grain in each ten drops. These injections will cause the rapid subsidence of specific lymphatic swellings, and the disappearance of localized eruptions. This is an important point to remember when the eruption occupies a conspicuous position such as the face, forehead, neck or hand. Injections very often relieve promptly the headaches and various neuroses of syphilis. They afford one also a way of giving mercury successfully where, as sometimes happens, mercury given by the stomach is depressing. In eye troubles they are beneficial, and in threatening cases of grave intra-ocular trouble, the author states that marvelous results sometimes follow the regional injection of calomel. Moreover, sublimate injections are often of much benefit in osseous, bursal, fascial and articular lesions of syphilis,

especially the earlier ones. In such cases, however, it is well to administer at the same time iodide of potash in full and increasing doses.

It will be clear, from what has been said, that the modern treatment of syphilis by an expert is a great deal more than the mere routine administration of mercury by the mouth in such doses as the patient bears best. Mercury is still the sheet-anchor of the treatment; but we have learned to use it more skilfully to obtain more of its therapeutic powers and fewer of its toxic effects. Doubtless improvements in the treatment of syphilis still will be made constantly; but such great ones have been made already that the knowledge of the chief remedy employed is only the very beginning of successful treatment.

NONA.

The REPORTER, April 12, 1890, contained a news item relating to an epidemic disease, the principal feature of which was prolonged sleep, that has recently made its appearance in Germany, several cases having occurred in the province of Hesse. The disease is called nona, and at first was thought to be a new one. The victims sink into a prolonged sleep, lasting for several days, and finally terminating in death. Marked evidences of pneumonia are observed at the same time.

The peculiar character of this disease will be best understood from the history of a case, which is reported by Dr. Braun, of Bolkenhain, in the *Deutsche Medicinische Wochenschrift*, March 27, 1890. The patient, a girl fourteen years old, was suddenly seized with severe headache accompanied with high fever. Great drowsiness soon overcame the child, and she fell into a deep sleep. If aroused, she would stare vacantly about her. She did not speak, and seemed not to recognize any one, and if let alone would immediately fall asleep again. On examination the pupils were found to be dilated, and they reacted but sluggishly to the light. The color of the lips and face was decidedly cyanotic; the tongue was dry and covered with a blackish coat; the respirations were rapid, but regular; the pulse was 110 in the minute. The temperature was very high, and there was perfuse perspiration. Urine and feces were voided unconsciously. The child had a stiff neck, and if her head was moved forward she gave evidences of pain. There was no paralysis. An extensive pneumonic infiltration of the middle and lower lobes of the right lung was found. The case was clearly one of pneumonia, combined with cerebro-spinal meningitis. The presence of meningitis and the involvement of the sensory centres accounted for the absence of cough and symptoms of pain in the chest.

When the patient was seen by Dr. Braun, the pneumonic crisis had been reached, and the chest symptoms soon began to improve. The meningitis did not improve. The child's condition became more and more alarming; there was no sign of returning consciousness; convulsions became frequent; and in six days after the first appearance of the disease the child was dead.

In view of the most recent researches in the etiology of pneumonia and cerebro-spinal meningitis, the disease "nona," as illustrated in the above case, is most interesting. In nona, pneumonia and meningitis occur simultaneously. At first the meningitis symptoms are most prominent, and completely mask the pulmonary condition, until the latter is well developed. Recent bacteriological researches indicate a close connection between these two diseases; the pneumococcus having been found in cases of cerebro-spinal meningitis as well as in pneumonia.

As the number of cases of inflammation of the lungs in Germany has been very great since the recent epidemic of influenza, the theory has been advanced that the present outbreak of nona may be due to the poison of influenza. Nona cannot be regarded as a new disease; but is a combination of two

known ones. The most active treatment exerts no apparent effect upon the course of the disease, a fatal issue having occurred in all the cases reported.

PRESCRIPTION WRITING.

The trial of a case of homicide has recently been concluded in the Paris courts, after having lasted for nineteen months. The facts of the case were briefly as follows: A druggist's apprentice, in putting up a physician's prescription, dispensed hydrochlorate of morphine, instead of hydrochlorate of ammonia. A child, two and a-half years old, was given the medicine and died. The testimony of experts was brought to bear upon the case, and it was finally proved that the child died from the ingestion of nearly half a grain of morphine. It was also shown that this drug had not been prescribed by the attending physician. A verdict of guilty was therefore rendered against the apprentice and he was sentenced to fifteen days imprisonment and a fine of two hundred francs; while the druggist was ordered to pay five thousand francs damages.

Our own country is by no means exempt from similar accidents, and cases in which a druggist's misunderstanding of a physician's prescription has been followed by disastrous results occur only too frequently. A large proportion of the profession seem to make a point of writing their prescriptions as illegibly as possible. The names of drugs are frequently abbreviated almost beyond recognition, and the quantities and directions are most ambiguous. Pharmaceutical journals frequently contain puzzles, in the shape of illegible prescriptions, which often defy interpretation.

The *Journal de Médicine*, of Paris, March 16, 1890, in commenting upon the case mentioned above, suggests certain rules which it would be well for physicians in this country, as well as in France, to conscientiously adopt. They read as follows:

1. Physicians should always write their prescriptions very plainly and legibly.

2. The names and doses of all toxic drugs should be written out *in full.*

3. Full instructions regarding the exact use of the remedy should be appended to every prescription.

The pharmacist, on his part, should never put up a prescription when there is the least doubt in his mind as to its correctness or meaning; be it either the signification of a single word, or an uncertainty regarding the manner of using the preparations. In all cases of doubt, he should obtain an explicit explanation before proceeding to put up the prescription. In case of an error on the part of the physician, either through inadvertence or ignorance, the pharmacist should refuse to dispense the prescription until the mistake has been corrected. Finally, all druggists would do well never to allow their apprentices or students to put up any prescriptions containing poisonous substances.

BERKS COUNTY MEDICAL SOCIETY.

The Berks County Medical Society held its last meeting at Kutztown, Pa., April 8, 1890, where its members were entertained by Dr. J. S. Trexler, who also delivered an address of welcome. The opening address was delivered by Dr. S. L. Kurtz, of Reading. Dr. E. P. Davis, of the Jefferson Medical College, Philadelphia, read an address on "Infants' Food;" and Dr. John T. Carpenter, of Pottsville, presented a paper on the "Administration of Chloroform." In the evening the Society was entertained at a banquet. The attendance was very good, and included, besides those mentioned above, Dr. W. L. Taylor, of the University of Pennsylvania; Drs. D. J. Dunott and H. B. Beeler, of Harrisburg; Dr. Daniel N. Bertolette, of the United States Navy; Dr. W. Erdman, of Allentown; Drs. Weidman, Reeser, Ermentrout and Rhoads, of Reading, and many others.

The Berks County Medical Society have awakened to new and increased activity of late, its members being anxious for its

standard to be high, and that it should rank among the foremost medical societies of the United States. There is no doubt but their hopes will be realized, for the profession in Berks Co. contains both the talent and energy requisite for the maintenance of a successful Medical Society.

MEDICAL MATTERS IN LOUISIANA.

For some time past the *New Orleans Medical Journal* has been urging, through its editorial columns, the establishment of a Board of Medical Examiners for the State of Louisiana, and the subject will probably come up for discussion at the next meeting of the State Medical Society of Louisiana. The *New Orleans Medical Journal* advocates the establishment of one Board for the entire State, and not one for each county, as there is in Alabama. The Society will probably protest against the present obligation imposed upon physicians to pay for a license to practice.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

MASSAGE AND THE SWEDISH MOVEMENTS; THEIR APPLICATION TO VARIOUS DISEASES OF THE BODY. By Kurre W. Ostrom, Instructor in Massage and Swedish Movements in the Hospital of the University of Pennsylvania and the Philadelphia Polyclinic and College for Graduates in Medicine. Illustrated. 8vo, pp. 97. Philadelphia: P. Blakiston, Son & Co., 1890. Price, 75 cents.

This little book gives, in an admirably clear and concise way, the essential parts of massage and the Swedish movements. Mr. Ostrom follows Mezger in dividing massage into four different manipulations: Effleurage (stroking), friction, pétrissage (kneading), and tapotement (percussion). Each of these manipulations is well illustrated by a clear wood-cut. The author gives the various movements as nine in number: rotation, pressing and shaking, flexion and extension, separating and closing, bending, raising, pulling, turning, and depression and elevation. Each of these movements is briefly described. The concluding portion of the book is taken up with the application of massage and the Swedish movements to various diseases of the body.

As a whole the book can be commended as a praiseworthy attempt to give the principles and practice of massage and the Swedish movements freed from any obscuring technicalities.

THROUGH THE IVORY GATE: STUDIES IN PSYCHOLOGY AND HISTORY. By William W. Ireland, M. D., Edin.; Corresponding Member of the Psychiatric Society of St. Petersburg, and of the New York Medico-Legal Society, etc. 8vo, pp. vii, 311. New York: G. P. Putnam's Sons, 1889. Price, $3.00.

The author states in his preface that the present book was written in prosecution of the views given in a previous book by him—"The Blot on the Brain." He seeks to show that Swedenborg, William Blake, Louis II, of Bavaria, Guiteau, Louis Riel, Gabriel Malagrida, Theodore, of Abyssinia, and Thebaw, King of Burmah, all suffered from some mental derangement: "They were led away by delusions or uncontrollable passions from the right comprehension of things, or the right line of conduct. In figurative language, they were visited by spectres which passed through the Ivory Gate."

The most interesting part of the book, of course, is that devoted to an analysis of Swedenborg's life. Swedenborg's pretensions to supernatural knowledge, the author says, were made in the light of a most sceptical time, the latter half of the eighteenth century. They were advanced in the clearest and most matter-of-fact way, indeed with much repetition in his numerous books, in his letters, and in his recorded conversations. Either Swedenborg was subject to delusions and hallucinations, or his pretensions to commune with the dead, and his claim to announce a new revelation were really founded on truth. To admit the latter, says Mr. Ireland, would entail the admission of a new religion.

The author believes that Swedenborg inherited a neurotic tendency from his father, who was himself a spirit-seer. Illusions or hallucinations seem to have been manifested in his childhood, and even to have been encouraged by his parents. His delusions were due to auto-suggestion coming from his powerful predisposition. The doctrines propounded by him were the result of the speculations of his powerful mind working while still unsubdued by morbid influences; the spirit-seeing and attendant puerilities were the result of hallucinations and delusions formed after his nervous centres had become diseased.

The stories of Louis of Bavaria, and of Guiteau are also very interesting, especially to alienists and psychologists. Doubtless some will take exceptions to certain of Mr. Ireland's deductions, but all must allow that he has written a most entertaining book.

ASTHMA CONSIDERED SPECIALLY IN RELATION TO NASAL DISEASE. By E. Schmiegelow, M. D., Consulting Physician to the Municipal Hospital and Director of the Oto-laryngological Department in the Polyclinic at Copenhagen. 8vo, pp. 90. London: H. K. Lewis, 1890.

The author first gives a brief but also very satisfactory historical review of the theories of asthma that have been held, and then presents in the same way an historical review of the reflex neuroses of the nose. He shows how the tendency, since Hack's publications, to lay chief stress upon the nasal disease in the production of asthma, has been modified gradually. In later years the opinion, he says, has by degrees gained ground that asthma is a disease of the central nervous system which may be excited to action by irritation of some peripheral nerve, as, for example, the branches of the trigeminal nerve distributed to the nasal mucous membrane. In human beings the irritable zone the irritation of which causes respiratory

reflexes, is situated in the anterior end of the inferior and middle turbinated bones and on the septum opposite and in analogous places on the posterior ends. Both zones of irritation are supplied with branches of the trigeminal nerve. The author mentions the experiments of Kratschmer, who examined these zones methodically and succeeded, by the use of irritating vapors, in provoking expiratory spasm of the muscles of respiration. The experiments were so conducted as to prove that the reflex arose from the nose alone, and that it ceased when the trigeminal nerves were cut. In explanation of the fact that no irritants of whatever kind have been able to cause asthma artificially, but only short tonic or clonic contractions of the respiratory muscles, the author suggests that the reason may be a want of predisposition in the central nervous system of the animals experimented upon. Practically, of course, this is equivalent to saying that in the absence of a sufficiently irritable condition of the "asthma centre" in the medulla oblongata the condition of the nose is powerless to provoke asthma. And this appears to be the author's opinion.

Schmiegelow's own experiences regarding the relationship between asthma and disease of the nose are represented by seventy-one cases, which are abstracted and tabulated. These cases of asthma occurred in a total of 653 of diseases of the nose. In the latter, five hundred and fourteen patients had chronic rhinitis, eight per cent. of whom had asthma; and one hundred and thirty-nine had nasal polypi, twenty-two per cent. of whom had asthma. He believes that it is possible in some cases, by suppression of the peripheral irritations, to stop definitely the asthmatic attacks; but that this in many cases first succeeds after a general strengthening treatment aimed at the central nervous complaint has been applied.

Dr. Schmiegelow has written a useful book, which throughout, as far as we can judge, is admirably moderate and just. We heartily commend it to all who are interested in asthma, especially in relation to disease of the nose.

New Remedies and Appliances.

In this department, notice will be given of Remedies, Food Articles, and Instruments or Surgical Appliances of which specimens are sent to the Editor; it will bear the same relation to these articles that the department of Book Reviews now does to books.

Wood-wool Dressings.

We have received from the Hygienic Wood Wool Co., of New York, specimens of a variety of their articles, including the wood wool, wood wool wadding, wood wool tissue, accouchement sheet, menstrual pads, and infants' diapers. In all these the most important feature is the use of finely divided wood as an absorbent material for medical, surgical and hygienic dressings. Ample experience with the material in Germany and Great Britain has shown that wood wool has very great power of absorbing liquids and that it is as safe for the physician to prescribe as it is comfortable for the physician to use. The articles sent us are well made, and abundantly deserve the attention of physicians.

Apparatus for Medication of Respiratory Passages.

Dr. J. H. Moore, of Cincinnati, sends a specimen of his patented apparatus for applying air impregnated with various medicaments to the nasal and naso-pharyngeal cavities. It consists essentially in a bulb, by means of which air is forced through a layer of liquid containing the medicament and then into the cavities to which it is intended to be applied.

The action is simple and calculated to effect the object. The box contains formulæ for use with the apparatus, but some of the ingredients could not possibly be carried out of the solutions in any quantity by the air passing through them.

Notes and Comments.

More Stringent Laws for Public Health.

In an article on the necessity of more stringent laws and stricter enforcement of existing ones for public health, in the *Boston Med. and Surg. Journal*, Feb. 20, 1890, Dr. G. H. M. Rowe says: The wave of advance that in recent years has marked every branch of medicine and surgery, has extended also to the interest of public health. The signs of the times point to better laws, a more intelligent understanding of them, and a greater willingness to accept and assist in their execution. The necessity remains of greater work and further progress. No apology is needed for renewing attention to a subject, to which much consideration has been given. It deserves thoughtful study so long as mortality from preventable causes remains at its present ratio. There has been during the last two years, much discussion by societies that meet in this room, about the various diseases communicable from person to person, and the writer judges that the interest has increased, rather than diminished.

The laws of our own State (Massachusetts) are far from perfect, but, in the main, they are very comprehensive, and if fully enforced as they now stand, would undoubtedly do much to improve the general health, and greatly reduce the death-rate from con-

tagious diseases. No better illustration can be pointed out than the result shown by our local Boards of Health in the enforcement of the laws relating to small-pox. The facts are too well known to require elaboration here as to what has been done in our own city. The laws are most scrupulously enforced on the appearance of a single case. It is taken by force if necessary, and removed not merely to a place of isolation, but to a special hospital, fully and at all times admirably equipped, not only for a single case, but for any number that may reasonably arise. The healthy are separated from the sick, vaccination enforced, the habitation and contents cleansed and fumigated, and unremitting vigilance shown to stamp out the disease at once. Too great credit cannot be given the Health Officers of Boston, for the practical banishment of what has been within twenty-five years a pestilence. During a period of twenty-eight years, more than 3,000 persons died in Massachusetts of small-pox. The yearly totals varied from twelve to as high as 300, with a yearly average of 107. During this time, similar methods were in practice as now prevail in the management of diphtheria and scarlet fever. Under the more intelligent and vigorous methods now existing, the deaths from small-pox during the last five years have been 8, 3, 1, 19 and 3; and the yearly average for the last fifteen years was only 19, or a reduction of 83 per cent. in mortality. If intelligent and efficient methods can be applied to the eradication of one contagious disease, why may they not by elaborative and vigorous enforcement, be accomplished with another, looking zealously to such diseases as have the greatest mortality, and which may be classed under the head of preventable diseases.

A comparison of the health laws of Massachusetts with those of other States shows a wide diversity. In many details they are more or less defective, and are general and insufficient. A general comparison will show that the laws of Massachusetts, New York, Illinois and Michigan lead in excellence. It might be considered a fault that the powers given under the laws are too often permissive and not obligatory. The statutes of Massachusetts make provision for local boards acting under the general supervision and co-operation of the State Board. They grant powers for such boards to carry out general and special laws for the control and suppression of contagious diseases. In a general way, they are sufficient for proper action, but from minor defects they are in too many cases inoperative. While the word "shall" is frequent, the potential "may" occurs too frequently. Many provisions are strongly and imperatively put, but in many cases there is no penalty, and hence may be ineffectual. Moreover, the capacity of the officers constituting the local boards especially in towns, is totally inadequate to carry out the powers placed in their hands. This is further made difficult not only by a want of stamina sufficient to resist social or political pressure for resistance, but by the labor and expense necessary to carry the provisions of the law to their full execution.

The laws and public sentiment concerning small-pox are well defined and adequate, but it must be conceded that there is too much indifference towards other contagious diseases, especially diphtheria and scarlet fever.

In looking at the results accomplished in England, a comparison of methods is naturally suggested, with the endeavor to find why so much more has been accomplished there than at home. Moulding public opinion, enforcement of laws, ways and means by hospitals and special appliances, cannot account for all their success. In examining English methods, the fact prominently presents itself that in cities like Glasgow, Sheffield, Manchester and Birmingham, where good results have been attained, the health officer of the town stands out as the pivotal agency. The Local Board occupies much the same relation to its community as our State Board does to our own State. The functions are general:—to note the interests of health, to make investigations as to disease or epidemics, to advise and to diffuse sanitary information. They have full power co-ordinate with any local boards or health officers, but from the vastness and diversity of the work it must reasonably come to pass that their acts are advisory and general. The local English boards occupy a similar relation to their own cities, proper allowance being made for the difference in organization between an American commonwealth and an English municipality. The English local board having decided upon the policy of action, its appointed health officer becomes the executive. The health officers of the English cities, are, I believe,

invariably medical men, since the duties of such officers are purely those requiring medical knowledge, and that of no mean order. This health officer takes the burden of the work, carries out the policy, and is left with full powers for action. Being selected by reason of his fitness, both for knowledge and executive capacity, perhaps shaping the course of action in the board itself, he is independent to push his work. The work of such officers as Drs. Gairdner or Roberts in Glasgow, shows what may be accomplished by the Executive when placed in the hands of a single-headed commission.

The success under this system naturally suggests the query whether such a policy would not accomplish better results in our own State, than the boards now constituted of three or more members. Municipal reform has for years demanded an executive head free from the constraint of two houses, always varying in complexion and policy. The brief trial given under the new charter has, I believe, received the commendation of the best citizens.

Domestic Filters for Drinking Water.

The *American Analyst*, March 20, 1890, contains an article by P. T. Austen, taken from the *Scientific American*, part of which, we think, well worth reproducing:

During the last few years the subject of water purification has received much attention, and successful methods have been introduced for filtering and purifying water on a large scale. Filtration on a small scale, while successful in many cases, comes, as a rule, under housekeeping, and the success or failure of the method will, therefore, often depend entirely on the operative ability of some domestic. While I do not wish to undervalue any of the excellent small filters now on the market, I desire to explain a simple method by which any housekeeper of average intelligence can make an inexpensive contrivance which will do its work in a way not easily surpassed by any filter that can be bought. It has been known for many years that the addition of a minute amount of alum to a water containing bicarbonate of lime in solution (and most natural waters contain more or less of this substance) will cause the formation of a gelatinous precipitate. This precipitate entangles and collects the suspended matters and germs, forming coagulated or agglomerated masses which are easily removed by simple filtration. Waters containing clay or mud which is so fine that a mechanical filter cannot remove it, when treated with a small amount of alum can be filtered perfectly clear through a coarse filter. The alum thus added is not left in the water, but is removed by the filtration, for its active constituent, the aluminic sulphate, is decomposed and precipitated by the action of the dissolved bicarbonate of lime. This should be well understood, although if a minute amount of alum were left in the water its effect would not be noticeable, and even if present in larger amounts, it would not be at all dangerous. The method of filtration is simple in the extreme. An oil bottle or any long, narrow-necked bottle serves for the filter. Tie around it a string soaked in kerosene, about half an inch from the bottom, set the string on fire, and hold the bottle bottom up. When the string is burnt out, the bottom of the bottle is thrust into cold water. If properly done, this causes the bottom of the bottle to split off evenly. The rim of the glass should now be burred off a little with a round file to remove any sharp edges that may be left. The bottle is then thoroughly cleaned and placed neck downward in a convenient support, as, for instance, through a hole bored in a shelf, or it may be allowed to stand in a wide-mouthed bottle, resting by its shoulders on the rim of the mouth. A small handful of cotton wool is now thoroughly wetted by squeezing it in water, and shreds of it are dropped into the bottle until a layer of about two inches deep has been made. The shreds should be dropped in carefully, so as to distribute them evenly, and not to let them pile up in the middle or at the sides. When enough cotton has been dropped in, a cup or two of water is poured in and the bottle gently tapped. This consolidates the mass and finishes the making of the filter-bed. The amount of alum needed to coagulate the water sufficiently for filtering need not, as a rule, exceed two grains to the gallon, and in many instances may be less, but in certain cases of very dirty waters, such as that of the Mississippi River, the amount of alum may be increased to four or even six grains per gallon. The alum is best kept in a solution of such a strength that a teaspoonful of it will contain a grain. To save trouble, the following prescription will enable one to get enough of the solution put up at any apothecary's to last for a considerable time:

℞ Alum . . . . . 128 grs.
Distilled water . . . . . one pint.

I may add that the expense of this prescription, including the bottle, should not exceed fifteen cents.

The treatment and filtration of the water is best done as follows: A gallon of water is placed in a clean tin pail and two teaspoonfuls of the alum solution are added. It will save time to make, once for all, scratches on the inside of the pail, showing the height of one, two or more gallons of water. It is then well stirred with a clean tin dipper. It is best to keep this pail and dipper for this use alone. They should be kept scrupulously clean and frequently well scoured with sapolio or a similar kind of soap. After mixing, the water is allowed to stand five or ten minutes, and then poured, by means of the dipper, into the filter. It will run through rapidly if the filter-bed has been properly made, and will be as clear as crystal, and not seldom will form an astonishing contrast with the original water. The first half-pint of the water passing through should be rejected. The filtered water may be caught in a pitcher or in any other convenient receptacle. A filter-bed will last a day, but it is not advisable to use it longer. Each day the used filter-bed should be thrown away and a fresh one prepared. The method may, of course, be applied to any of the many filters in use, simply adding to the water to be filtered one or two grains of alum to the gallon. It will be a poor filter, indeed, that will not filter clear after this addition. Of late, attention has been drawn to the latent dangers in ice. It has been found that this apparently harmless and attractive substance may fairly reek with disease germs and filth of all kinds. Unless it is known from whence the ice comes, its use may be more dangerous than the use of water. Ice is sometimes derived from water which no one would think of drinking, as, for instance, from ponds in cemeteries and from rivers in the neighborhood of sewer outlets, and as a result may be indescribably foul. Aside from the danger of germs lurking in ice, there is risk in the indiscreet use of water cooled to an abnormally low temperature, since functional disorders are often caused by the drinking of very cold water. No water is so refreshing as a mountain spring, and one reason of this is that its temperature is just right. It is well to take hints that are given by nature, and the hint that the best temperature of drinking water is about fifty degrees Fahrenheit is a good one, and worth following.

Diagnostic Value of Tolerance of Iodides in Syphilis.

In *L' Union Médicale* for October 31 and November 2, 1889, is to be found an article by Dr. J. William White on the diagnostic value of the tolerance of iodides in syphilis. The paper is a translation and amplification of one on the same subject published by him in this country some months ago. It was read at the French Congress of Dermatologists and Syphilographers held in Paris last August. The assertion of Dr. White, that the presence or absence of iodism is of no diagnostic value in these cases of suspected syphilis in which large doses of iodides are given tentatively seems to have met with the very general endorsement of the profession, including not only the venereal and genito-urinary specialists, to whom Dr. White's paper was more particularly addressed, but also the neurologists and general practitioners. There has undoubtedly been a more or less widespread belief that tolerance of the iodides indicated the existence of syphilis, and if, as it would seem to be the case, this is incorrect, Dr. White has rendered a valuable service to the profession in calling attention to the subject. His position is strongly supported by such men as McCall Anderson, Hyde, Keyes, Otis, Sturgis and others, and would appear to be consistent with both theory and clinical facts.—*University Medical Magazine*, Jan., 1890.

Sanitary Convention.

The fourth State Sanitary Convention of Pennsylvania will be held at Norristown, Pa., May 9 and 10, 1890, under the auspices of the State Board of Health, acting in conjunction with the Board of Health of Norristown.

It is intended that the essays and discussions shall be entirely of a practical and popular character. The object of the Convention will not be scientific research, but the unfolding of the results of such research with clearness and simplicity. It is especially desired that women, on whom so much of the hygiene of the home depends, shall attend. The occasion will be one of especial interest and profit to health officers and municipal authorities, who, it is trusted, will avail themselves of the opportunity.

NEWS.

—Dr. William R. Wilmer, formerly Naval Officer of the Port of Baltimore, died April 25.

—There were nine cases of measles among the immigrants at the Barge Office in New York, April 26. They were all imported on the steamer Teutonic.

—Dr. David Gilbert Adler, a graduate of the Jefferson Medical College in 1889, died in Philadelphia, April 22, at the residence of his father, Dr. John M. Adler.

—The funeral of Mrs. Keziah Halstead, aged 63, a nurse in a number of Southern hospitals during the rebellion, and widow of Dr. Joseph Halstead, of Chicago, took place April 23, at Oceanic, N. J.

—The movement for the establishment of a special training school for nurses in the insane department of the Philadelphia Hospital has taken practical shape, and the school will probably open early in this month.

—A dinner was given at the Hall of the College of Physicians of Philadelphia, April 22, the occasion being the presentation to the college of life-size portraits of Dr. D. Hayes Agnew and Dr. S. Weir Mitchell.

—The twenty-seventh annual commencement of the New York Medical College for Women took place April 22. Following the Dean's address came the administration of the Hippocratic oath to fifteen graduates.

—Dr. Nicholas Senn and Dr. Christian Fenger have been elected regular Professors of Surgery in the Chicago Polyclinic. In addition to clinical work, they will present a special course in abdominal surgery twice yearly.

—Dr. R. S. Marshall, a prominent physician of Pittsburgh, Pa., a graduate of Bellevue Hospital Medical College, in 1874, committed suicide, April 22, by shooting himself in the head. Illness is given by his family as the cause.

—The Ladies' Aid Society of the Building Fund Committee of the Philadelphia Polyclinic and College for Graduates in Medicine gave an afternoon tea, April 22, in the Hotel Stratford, to raise funds for the completion of its new hospital building.

—An epidemic of typhoid fever is said to have broken out in Augustana College, at Rock Island, Illinois. One student has died, and many others and a professor are dangerously ill. Defective sewerage in the main building is said to be the cause, and it is being remedied as quickly as possible.

—The resignation of Professor George W. Miltenberger was accepted April 25 by the faculty of the University of Maryland. He was then unanimously elected Emeritus Professor of Obstetrics and Honorary President of the University. Dr. Miltenberger has been connected with the University of Maryland for fifty years.

—Malignant diphtheria is said to have been recently epidemic in the village of Vining, Minn., which has a population of about 150 persons, nine-tenths of whom were afflicted with the disease. There were twenty deaths between April 1 and April 23, and thirty altogether. The funerals of all the victims have been public and largely attended.

—The Board of Health of Philadelphia, on April 22, directed its Chief Milk Inspector to prosecute seven dealers who were alleged to have continued to sell diluted, skimmed and colored milk in violation of the Act of Assembly, after having been notified of the same. It was resolved to ask City Councils to pass an ordinance to prohibit the sale of adulterated or impure milk.

—The health of Constantinople has, for many months past, been below its average standard. The sanitary appliances introduced in the construction of the houses appear to be deplorably imperfect, and their wretched arrangements are not assisted by an efficient supply of water. As regards external drainage, Constantinople is finely situated, but there are many quarters where the gradient of the sewers is too slight to ensure a rapid outflow.

—The Charity Hospital, of Norristown, Pa., some time ago adopted a provision that the medical staff of the Hospital should be selected from the Montgomery County Medical Society. Subsequently the Hospital Association was appealed to in a petition to rescind the rule so as to admit homœopathic physicians. The matter was formally discussed and attracted general local attention. A committee to which the petition was referred presented a report at a meeting of the Association, April 17, in which they say they are forced to believe that two schools of medicine in a public hospital is impracticable; that it would lead to endless conflict and confusion. They, therefore, declined to recommend any change of rules of the institution, thus debarring homœopaths from practicing there.

BURN BRAE

A PRIVATE HOSPITAL

--FOR--

MENTAL and NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

EXTENSIVE AND BEAUTIFUL GROUNDS, affording perfect privacy and pleasing variety. House and surroundings unusually attractive and cheerful. Heat, light and ventilation perfect.

A PLEASANT, SAFE AND HEALTHFUL HOME,

With constant professional supervision. Music, games, open-air amusements, boating, etc., are provided for patients.

THE OLDEST INSTITUTION OF THE KIND IN THE UNITED STATES.

Both sexes received. A limited number of opium habitues admitted. Pleasant companions for female patients.

LOCATED A FEW MILES WEST OF PHILADELPHIA,

At Primos Station, on the Philadelphia and Media Railroad, from Broad Street Station, Philadelphia, Pa.

POLYURIA OF INTERSTITIAL NEPHRITIS.—DIABETES INSIPIDUS.—TUBERCULOSIS OF THE BOWELS.[1]

BY JAMES B. WALKER, M. D.,

PROFESSOR OF THEORY AND PRACTICE OF MEDICINE, WOMEN'S MEDICAL COLLEGE; VISITING PHYSICIAN TO THE PHILADELPHIA HOSPITAL, ETC.

Polyuria of Interstitial Nephritis.

Gentlemen: The first case I wish to show you this morning is a man, sixty years old. His parents both lived to about the age of ninety years. He is Irish by birth, and a sailor by occupation. His health has always been good. He denies any specific history, and has never had any sickness. Twelve years ago he suffered from an hemiplegic attack involving his whole right side, including his face. With this there was aphasia. He has never fully recovered from this attack. For the past six weeks he has had some cough and hemoptysis with some dyspnœa. With this there has been profuse expectoration; his sleep is disturbed; he has lost no flesh. This part of his history, however, has no reference to his actual trouble. He is suffering from polyuria. Here is a record running over a series of days, showing how much urine he has passed. On October 27, 1889, he passed 66 ounces, and from that time on it has varied up to 70 and 80 ounces. The character of his urine is as follows: On February 12, the urine contained no abundant sediment, but on microscopical examination, triple phosphates and some granular débris were found, also a trace of albumin; its reaction was faintly acid. In December it was alkaline in reaction, but with no albumin. On November 28, the specific gravity was 1.008,

[1] Delivered at the Philadelphia Hospital.

triple phosphates and a trace of albumin were found, but no casts; the reaction was alkaline. On October 24, it contained no casts, but a trace of albumin, and a small amount of white sediment; the reaction was neutral. On September 13, hyaline and pale, granular casts were found, with some albumin; the reaction, acid and the specific gravity was 1.010. The first record was taken September 5, when the specific gravity was 1.010, and phosphates and hyaline casts were found, and a decided ring of albumin was produced by the acid test.

The present condition of the case is as follows: The amount of urine voided is greater than normal; it contains no albumin; the specific gravity is below normal. His temperature chart shows an occasional slight amount of fever. Most of the time since August, the amount of urine passed has been over 60 ounces a day. With this is a history of a slight hemiplegic attack involving the whole right side of the body. With such a history in a person 60 years of age, what is the diagnosis to be arrived at? There is no marked atheroma of the surface vessels, the tortuous temporal artery being the only change noticed in the vascular system. That he has fragile vessels, however, is shown by the fact that he has had one attack of hemiplegia.

What, now, is the cause of polyuria? There are two causes. The first of these is a high arterial tension, as seen in cases of interstitial nephritis; the other is a low local tension as seen in polyuria associated with diabetes insipidus where there is a loss of the watery constituents of the blood due to a want of vaso-motor tone in the kidneys, often from centric trouble. In such cases there is no albumin in the urine, which has a very low specific gravity, 1.003 to 1.005; and is associated with incessant thirst, rapid emaciation and dryness of the skin, but no atheromatous vascular changes. This condition is often transient and undergoes rapid improvement, in other cases it is persistent and untractable. Then we have polyuria in diabetes mellitis, where there is a large amount of urine with a high specific gravity, and loaded with sugar. There are other conditions in which it is found, as in acute alcoholism; and in amyloid degeneration of the kidney, where there is a tendency for the blood to leak through the hyaline and modified vascular walls in the kidney. But in the ordinary chronic conditions in which we find increased urination, the condition is one of the three first mentioned.

This patient has had a polyuria since last August, passing nearly twice the normal amount of urine. This is a small amount to pass in diabetes, but it is a large amount in a case of ordinary Bright's disease. Formerly all cases of albuminuria were classified as Bright's disease, but now we recognize the existence of albuminuria from transient causes without any disease of the kidney. Bright's disease includes any alteration of the essential structures of the kidney. These structures are three in number. Thus we have the excretory system, comprising the kidney cells, the parenchyma of the organ. Then we have the vascular system, the vessels which carry the blood to these cells, whose débris constitutes the essential part of the secretion. The third structure is the connective tissue constituting the enclosing capsule. The enveloping capsules of the vessels, and the separating and uniting capsules of the tubules.

Inflammation of the first of these structures constitutes the so-called parenchymatous nephritis, that is, disease of the essential tissues of the organ. Thus pneumonia is a disease of the parenchyma of the lung, and acute yellow atrophy, of the parenchyma of the liver, so this is a disease of the parenchyma of the kidney. Tubular and desquammatic nephritis are synonymous with parenchymatous nephritis. The tendency to desquamation gives rise to the second name, and often there is but very little epithelium left in the tubes. It is also called catarrhal nephritis. This may run a course, pure and simple, with rapid destruction to life or restoration to perfect health.

Then we may have disease beginning in the blood-vessels. Amyloid degeneration is essentially a disease of the blood-vessels. It is seen also in the intestines, liver and spleen, always beginning in the vascular walls. The third form of the disease is where the connective tissue is involved in the inflammation primarily. Some say that we can only have tubular disease as a result of a primary disease of the connective tissue. Two of these forms are nearly always commingled, namely, disease of the tubules and of the capsule. Interstitial or granular nephritis and tubular nephritis are more or less always commingled, except in the rare acute condition I have mentioned above. The case before us presents an interstitial nephritis with a tubular nephritis in a slight degree.

Interstitial nephritis of long duration is absolutely incurable, but amenable to treatment, and the patient may be kept in a fair condition, death resulting from some intercurrent condition, such as uremia, or vascular changes elsewhere, inducing apoplexy. When a patient presents himself, and we find a trace of albumin present in the urine and persisting or recurring, but with no sign of dropsy, we may rest assured it is a case of interstitial nephritis. If we find a history of polyuria, with no dropsy, and no, or but little, albumin, and the urine of a low specific gravity, with a pulse of high tension or cardio-vascular degenerations, we may also set it down as being chiefly a case of interstitial nephritis. These constitute the large majority of cases of Bright's disease. To one case when the parenchyma is chiefly involved there are three to five where the connective tissue chiefly suffers.

The characteristics of this condition are an increased urination due to the influence exerted on the circulatory system by an imperfectly depurated blood. The increased arterial tension results in a polyuria. The kidneys are not doing their work, and some material is retained in the blood, uric acid perhaps, which raises the arterial tension by producing a spasm of the muscles of the arterioles at the termini of the arterial circulation. Hypertrophy of the left ventricle results from the stimulus to development caused by increased effort needed to open the aortic orifice. Many cases of atheroma of the vessels are induced by this condition of the vascular system. The tunica intima is first invaded; it becomes roughened, local clots are formed, emboli result; or partial rupture occurs with the formation of miliary aneurism; or larger aneurisms may be formed; or an actual rupture of the entire vessel takes place, with resulting hemiplegia. These cases are the most amenable to treatment of all the renal cases. We can assist them if we cannot cure them. Whenever albuminuria presents itself the case at once assumes a serious aspect; as this indicates a tubular nephritis in addition. A very small amount of albumin only is capable of changing the case into one of great gravity. If œdema is associated with this, it is probably due to amyloid disease, or to a late change in the interstitial cases.

It is favorable that the patient should void this large amount of urine, and no efforts should be made to stop it. It is well to give him Poland water or Apollinaris or other medicated water in order to further depurate the blood. We thus favor this increased formation of urine.

Diabetes Insipidus.

The next case is one of polyuria also, in which, however, there is no albumin. It has recently arisen in a patient suffering from malaria. Here is a patient presenting attacks of chills associated with fever, especially in the afternoon, and at intervals periods of decided fever. Suddenly he develops polyuria. On February 7 he passed 160 ounces of urine in twelve hours. On Feb. 8, during twenty-four hours he passed 240 ounces. The following days the amounts passed were 180, 220 and 170 ounces. The specific gravity of the urine has been low, 1.004, 1.010, 1.007 and 1.004. The urine has a faint odor, is alkaline, contains no albumin nor sugar, and is almost colorless. Polyuria due to diabetes insipidus differs from polyuria arising from interstitial nephritis in the fact that it is acute and sudden and is usually a transient condition.

This other patient has polyuria also, due to diabetes insipidus. The specific gravity is low, 1.003 or less. It is generally lower than it is in interstitial nephritis. This patient has been suffering from malaria. This is one of the causes of diabetes insipidus. It may also be a cause of interstitial nephritis, however. His skin is not very dry; his tongue is pale, but not dry; he is very thirsty, especially at night. As regards treatment, in simple polyuria ergot has given the best results. We will place this man on from ten to twenty drops of the fluid extract three times a day.

Tuberculosis of the Bowels.

Last week I showed the class a case of disease of the alimentary tract, associated with a diarrhœa which had lasted over a long period. The patient was emaciated and phthisical-looking. His abdomen was slightly tympanitic over the small bowel, that is from the suprapubic region to the umbilicus. The disease had existed about ten months, with from four to nine movements of the bowels per day. Medicine arrested this a little, but had no permanent effect. On account of the fulness in the centre and lower portion of his abdomen we thought that the small bowel suffered most. There was tenderness over the entire abdomen, but especially in the centre. The case seemed to be one of

interitis. We considered the question of tuberculosis of the bowel, but as he had a fever chart with a normal morning temperature we laid aside this thought, but did not discard it altogether, merely not laying much stress upon it. The next day the man died. His abdomen swelled rapidly, and in it were found four quarts of fluid which was not all there when I showed him to you.

The entire alimentary tract from the stomach down was invaded with the disease. In the rectum were large surface ulcers and nodular patches. On the colon were a few ulcers at intervals of a few inches, from the size of a small pin-head up to that of a ten-cent piece, or greater. The salivary glands were not as extensively involved as in chronic dysentery. There was the same deep staining as seen in chronic inflammation of the bowels. In the transverse colon were three large ulcers extending down and into the muscular coat. From here there was no involvement of the colon to any extent until one ulcer was found above the cæcum, and two at the ileo-cæcal valve. The appendix was free at the extremity. The small bowel showed ulcerations all the way along its extent, and closer together than in the large bowel. Considerable hyperemia also existed here. These ulcers all had their long axis in a transverse direction. Their edges were thick and prominent, and surrounded by numbers of small miliary bodies. Numerous clusters of tubercles were found. The peritoneum was thickened and roughened. The valvulæ conniventes were eroded and destroyed where ulcers existed.

This was a very interesting case, illustrating the condition which a week ago we were considering. One feature of the case should have led us to make a diagnosis of tuberculosis, and that was the persistency of the inflammation in the smaller bowel for so long a period. This should always lead us to suspect the presence of tuberculosis where hygienic and medicinal efforts for relief are unavailing.

—Sodium carminate for staining nervous tissues, en masse, in place of the usual borax carmine, alum carmine and Delafield's hæmatoxylin, is advocated by Dr. Geo. A. Piersol in the December, 1889, number of the *Microscopical Journal.* Dr. W. B. Canfield describes the microscopical analysis of urine in the same number of that journal.

REMOVAL OF UTERINE APPENDAGES.[1]

BY E. E. MONTGOMERY, M. D.,

PROFESSOR OF GYNECOLOGY, MEDICO-CHIRURGICAL COLLEGE; OBSTETRICIAN TO THE PHILADELPHIA HOSPITAL.

Gentlemen: This woman is twenty-four years old, unmarried, and has had pain at her menstrual periods for some years, together with menorrhagia. Two months ago she began to suffer severe pain in her right side which she then thought was due to a prolapse of the uterus. Examination, however, does not disclose such a displacement, but the uterine appendages are inflamed, prolapsed and exceedingly tender. One tube is considerably enlarged, quite tortuous and at times gives her great agony. From this she has suffered for years in lifting, straining and violent movements. When we consider the inflammatory condition of these organs and their influence upon the general economy, it is not surprising to find such an individual living the life of an invalid. Both patient and general physician hesitate to accept an operation as the only method of relief; and various procedures have been suggested to provide escape from it. Of these, electricity is probably the most promising; but we cannot see how this agent even will be capable of restoring the functions of tubes which have occluded by lymph exudations which guard the peritoneal cavity from infection with an irritating fluid contained within the tubal sacs. It is difficult to believe that a restoration to normal condition, or even one approaching it, can be accomplished by such measures in a tube the seat of a hydro-, a hemato- or a pyo-salpinx. Therefore, while I thoroughly deprecate any rash or useless operations, yet, as these organs are already diseased beyond recovery, I feel that by their removal I am not uselessly mutilating my patient, but am merely relieving her of organs that are useless—and even worse than useless—painful and dangerous. A pus sac may open through the vagina; but, unless this be kept open, it will recur and bring on the symptoms by which it was previously accompanied. Consequently we do not hesitate to operate on this patient. Her bowels have been thor-

[1] Delivered at the Philadelphia Hospital.

oughly moved and thorough cleanliness has been obtained by washing with soap and water; especially over her abdomen and external genitalia. These parts are now again washed in a bichloride solution. I have the table, upon which are my instruments, close beside me, so that I can reach them as they lie in the pans, covered with plain hot water; and in this way save having to resort to the use of a middle man who might possibly prove a source of sepsis. I cut through the skin and superficial fascia, always trying to strike the linea alba. If, however, I do not cut down on this line, I do not fret about it. I next cut through the other fasciæ and peritoneum with probe-pointed scissors. Introducing two fingers into the wound, I feel for the fundus uteri as a landmark, and, passing outward to the left, a mass is felt which is closely adherent; indeed completely encapsulated. My fingers are passed over this and enucleation made from below upward. As it is brought out you see pus exuding from the Fallopian tube —a clear demonstration of its character and of the importance and necessity of the operation.

I use as small a ligature for the pedicle as will serve the purpose. The ovary and tube are cut away, and, finding that bleeding is securely prevented, the ligatures are cut short.

The opposite side is now investigated, and the right ovary and tube are found adherent and enlarged. Experience has demonstrated that where inflammatory trouble exists in one tube sufficient to require removal, the remaining one will sooner or later develop trouble that will necessitate a repetition of the operation. In the present instance the condition amply justifies removal of the second tube and ovary.

The peritoneal cavity is flushed out with simple hot water, to remove the blood which has oozed from the torn adhesions and to decrease the possibility of infection from the pus tube. The stitches are introduced through all the fasciæ of the abdomen, at about one quarter of an inch apart. They are then tied from below upward, care being taken that the wound surfaces shall be carefully approximated, and the parts antiseptically clean. The wound is dressed with: 1, iodoform and iodoform gauze; 2, dry bi-chloride cotton; 3, burnt cotton; 4, adhesive strips; and finally, 5, a crinoline binder, which is better than flannel, and which is pinned from above downward with safety pins. The pressure of this binder lessens the danger of venous oozing in the abdomen.

The patient is now put in bed, and hot bottles are put to her feet and around her. Later she will be given a limited supply of liquid food by the rectum. Nothing is to be administered by the mouth until the nausea caused by the ether and the handling of the ovaries has ceased. After the first forty-eight hours she will receive by the mouth some liquid food, among the varieties of which I am very partial to bovinine. Avoid the use of morphine, unless the pain be very excruciating. It often has the result, by checking the secretions, of making the temperature go up. If, however, there is an elevation of temperature and signs of peritonitis, I generally give a saline cathartic, in order to deplete the blood-vessels and to clear out the alimentary tract. If there were many adhesions and much pus a drainage-tube should be used, taking care to place it in such position that the lowest portion of the peritoneum can be reached. If necessary, the cavity may be irrigated with hot water or a disinfecting solution every few hours.

In cases of extensive adhesions it is sometimes preferable to keep the abdominal cavity filled with a solution of boro-glyceride. With the cavity filled with the fluid the intestines do not lie in contact continuously, and consequently there is less danger of the formation of unfortunate adhesions. The torn, denuded peritoneum is renewed. This is accomplished by frequent irrigation, permitting the tube to remain filled with fluid.

COMMUNICATIONS.

PATHOLOGY OF TYPHOID FEVER.[1]

BY CHARLES F. J. LEHLBACH, M. D.,
NEWARK, N. J.

Some questions relating to the causation of *typhoid fever* cannot be fully discussed without reference to the pathological anatomy of the disease and to some of the minute histological changes accompanying its progress. In fact these pathological changes stand in direct causative relation to the complexus of symptoms which makes

[1] From a paper read before the Newark, N. J., Medical Association.

up our conception of typhoid fever. On the other hand, the question of what causes these lesions, brings up at once the whole subject of their external cause. Without attempting to give a review of the various controversies that mark the progress of medicine in relation to this disease, it may be stated that typhoid fever, its symptoms and its lesions, are due to the presence of a poison in the system, a poison of a specific nature, which is either generated in the body itself, or introduced from without.

The external origin of the poison is, at present, generally conceded; although it is but fair to state, that up to a time approaching nearly the end of the past half of this century the view that the poison originated within the body was entertained by many eminent observers and medical philosophers.

The most characteristic lesion of typhoid fever consists in the changes in the lymphatic follicles, in the inflammatory enlargement and subsequent degeneration of the solitary glands and Peyer's patches or agminated glands.

To understand fully these changes and some of the influences which will hereafter be made, it may be worth while to glance for a moment at the histological relations of these glands. They are, in the first place, *absorbent* glands in contra-distinction to Brunner's glands and Lieberkühn's follicles, which are organs of secretion of the intestinal fluids. The structure of the solitary glandules and of those forming Peyer's patches is the same. According to Dalton, they have a close relation with the lymphatics of the intestine. The lymphatic vessels coming from the villi form a plexus in the substance of the mucous membrane, from which branches pass to the follicles and ramify over them, forming another plexus upon their investing capsule. Owing to the analogy in structure between these bodies and portions of the lymphatic glands, as well as to the fact that the lacteals from the neighborhood of Peyer's patches are more numerous than those from other points of the intestine, the closed follicles are generally regarded as belonging to the system of the lymphatic glands. They furnish no secretion to the intestinal cavity, but are connected in some way with the elaboration of the absorbed materials. Now the minute changes which take place in the course of the intestinal lesion in typhoid fever are as follows (Delafield & Prudden): "At first the blood-vessels around the follicles are dilated and congested, while the follicles are swollen, and the epithelium falls off. Then the follicles increase largely in size from a growth of new cells. The new cells are, in part, similar to the lymphoid cells, which normally compose the follicles, in part are large, rounded cells, some of which contain several nuclei. The production of new cells is not confined to the follicles, but extends also to the adjacent mucous membrane. In many cases also, little foci of the same cells are found in the muscular, sub-serous and serous coats. This increased number of cells compresses the blood-vessels and the parts become anemic. Soon the cells degenerate either by granular degeneration of individual cells, or by gangrene of part of a follicle. In either case the degenerated portion is eliminated into the intestine, and leaves an ulcer of which the floor and edges are infiltrated with cells. After this the cell-growth goes on, and the ulcer enlarges, or the cells are gradually replaced by connective tissue, and cicatrization follows." You will see phases of this process in the sketches of ulcers handed round, and the actual microscopic sections will be ready for your inspection later on.

In more severe types of the disease the enlargement of the follicles ends in ulceration. This takes place in two ways:

(a) The enlarged follicles often break down, and discharge into the intestine. In this way are formed small ulcers. These ulcers increase in size by the same softening process which gradually attacks their edges, and in this way ulcers of large size may be formed. The ulcers may extend outward only to the peritoneal coat, or they may involve the peritoneal coat also and perforate.

(b) In the severest forms of the disease, considerable portions of the enlarged patches slough, are detached and leave large ulcers with thick, overhanging edges. The slough may involve only the follicles or it may involve also the muscular and peritoneal coats. These ulcers also may afterwards increase in size, and several of them may be joined together. "If the patient recovers, the ulcers cicatrize, their edges become flattened, their floors are converted into connective tissue covered with cylindrical epithelium."

With this description of the process of the main lesion of severer forms of typhoid fever, we can readily understand and explain the various symptoms which it presents: the tympanitis, the meteorism, the gurgling

sound, the tenderness in the right iliac fossa and the peritonitis at times. But in milder forms these abdominal symptoms need not be so marked, and these are the cases which often give rise to doubt as to whether they are really typhoid or not. For—according to the same authors—"if the disease was mild and the enlargement of the follicles moderate, the enlargement gradually disappears and the follicles resume their normal appearance. In moderate enlargements, the retrograde processes affect first the follicles and leave the septa between them still swollen and prominent. This gives to the surface of a patch a reticulated appearance. After a time, however, the entire patch becomes flattened and uniform. . . . The solitary follicles, also, or the separate follicles of a patch soften, break down, and their contents are discharged with some attendant hemorrhage. This leaves a bluish-gray pigmentation in the situation of each follicle. This pigmentation may remain for years."

Thus the cause of so much variation in the gravity of the symptoms of the disease may be readily understood, when we bear in mind the variation in the number of glands affected, the degree of their inflammation, and the succession of the process to rapid healing or to destructive ulceration. The not unfrequent, so-called relapses of the fever—as far as my experience goes—seem to be mainly due to, and to coincide with, the invasion of new glands, with a repetition of the intensity of symptoms.

Leaving the intestinal lesion in its causative relation to the symptoms of the disease, I will now refer to only one more of the pathological changes in the various organs —that of the spleen; and as I intend to draw some inferences therefrom relating to the *external* cause of typhoid fever, I here call attention to the anatomy of the spleen and its vascular arrangements.

"The spleen," says Prudden, in his manual of Normal Histology, "although differing in many important and probably most essential particulars from the lymphatic glands, yet presents many striking analogies with them. Like them it presents on cross-section, to the naked eye, a fibrous envelope—the capsule—from which septa and trabeculæ pass into the organ, enclosing irregular spaces. Here, also, we find the spaces between the septa followed with a soft substance presenting two distinct modes of arrangement; we find first, irregularly scattered through the organ, small grayish globular or elongated structures, called Malpighian bodies, or follicles; and second, between these, filling up the remaining space between the trabeculæ, a soft, red tissue called the pulp. Finally, blood-vessels."

We must notice the fact that the splenic artery is remarkable for its large size in proportion to the size of the organ, and also for its tortuous course. "If," says Prudden, "we carefully study the walls of the smaller arteries, we find that in certain parts they undergo a singular modification: at first the connective tissue sheath and the adventitia become very loose in texture, and their masses become filled with spheroidal cells, resembling lymph-cells—this is called lymphoid infiltration of the walls of the arteries; then we find that at certain points this infiltration becomes quite extensive, the intercellular substance assuming the character of reticular connective tissue; and thus distinct spheroidal or much elongated swellings are formed either around or at one side of the arteries—these are the splenic follicles or Malpighian bodies. The blood, after its exit from the fine arterial twigs on which the Malpighian bodies are found, passes, through the intervention of the capillaries, probably directly into the meshes of the pulp-cords; and after circulating here among the cells, —not in distinctly walled channels—it finally finds its way into the cavernous veins, whence it passes out of the organ through the large efferent veins at the hilus."

Now the spleen in nearly every case of typhoid fever is enlarged. This enlargement begins soon after the commencement of the disease, increases rapidly until the third week, remaining stationary for a few days, and then diminishes. The organ is congested, of a dark-red color, and of firm consistence, while it is increasing in size. After it has reached its maximum size, its consistence becomes soft, and there is a considerable deposit of brown pigment. The enlargement appears to be due to the congestion, and to an increase of the normal elements of the spleen.

There is another anatomical fact in the vascular arrangement of the spleen to which I must allude for later reference. It is the arrangement of the splenic vein in its bearing to the relative rapidity of the flow of blood into the portal vein. It commences by five or six large branches, which return the blood from the substance of the organ. These, uniting, form the main trunk which, passing behind the upper border of the pan-

creas, and receiving gastric, pancreatic and other branches unites with the superior mesenteric vein at nearly a right angle, to form the portal vein. Hence the rapidity of the flow of blood is, in the first place, diminished by the angular meeting of these two currents; and, secondly, the rapidity of the flow is entirely uninfluenced by the direct suction force of the diastolic action of the heart as is the blood of the vena cava. The large inflow of blood, then, through the splenic artery, the largest branch of the cœliac axis, the second given off from the abdominal aorta, with its tortuous circulation through the organ, and its retarded outflow through the portal circulation, form conditions which may have an important bearing upon the presence, movement and elimination of a poison introduced into the blood.

The introduction of so much elementary matter is necessary to connect the links of subsequent argument. How is the poison of typhoid fever, which gives rise to the pathological changes characterizing the disease, introduced into the system? The evidence in the literature of the history of typhoid epidemics or endemics, and in the thousands of accumulated accounts of sporadic cases, is overwhelmingly demonstrative of the fact that the poison of typhoid fever—whatever it may be—is often introduced into the system by means of water used for drinking purposes. And we are not justified in assuming that this introduction, or the contamination of the water is only an accidental concurrence. Chemical examination has failed to discover the nature of the poison in drinking water to which cases of the disease have been clearly attributable. But, in all cases under my own observation, when everything pointed to the introduction of the poison through these means, an ordinary examination by simple tests showed the existence of chlorides and ammonia above what is admissible—a proof not only of contamination by organic decomposition, but a proof also of the greater probability of such water to favor the growth, development, or, at least, the viability of pathogenic germs accidentally introduced into it. "In many instances of infection through the water," says Flint, "it has been possible to show some communication or leakage between a well used for drinking purposes and a privy-vault, cesspool, sewer or drain. Instances of the introduction of the poison by means of milk have been numerous."

During the autumn of 1888 I was forcibly impressed with the possibility of the introduction of the typhoid fever germ in this manner. I was attending a young man, twenty-four years old, suffering with typhoid fever, at Elizabethport, N. J., near the Central R. R. Station. The ground is swampy, well-water is used exclusively by the people living in the street where my patient resided, and goats form part of the domestic household in nearly every family. Numerous cases of typhoid fever had occurred in the street, a number fatal.

Now, on inquiry as to how the dejections of the patients were disposed of, I was told that great care was taken not to contaminate the privies; but that the dejections were emptied and spread over the soil in the lots in the rear of the houses, to which the goats had free access, to pick their food. The germs may lie dormant there even during winter, because, as Prudden has demonstrated by his exhaustive researches, freezing does not kill the germs, and thus, with the thaw of spring and the new grass, the dormant microbes may be called into new life in the goats' intestines, be absorbed into the blood, and carried into the lacteal secretion, and thus keep up the vicious circle of organic poisoning.

My views in regard to the causation of typhoid fever by water contamination have been repeatedly expressed, and also my emphatic condemnation of the use of well-water in this or any other large city, and my firm belief, based upon observations in a practice of over thirty years, that our aqueduct water, derived from a large, quickly-flowing stream, constantly subject to the purifying influence of sunshine and aëration, never has been and never will be the cause of infection by pathogenic germs. I have now in my possession the history of thirty-one cases of typhoid fever treated during the autumn and winter of 1888–89, in the German Hospital, of this city, with names and residences, and this is the resumé: Of the total number—31—there were

drinkers of	
Well-water exclusively,	23
Doubtful,	4
Aqueduct water exclusively,	2
Mixed,	2

I need not extend my remarks in this direction. If there is anything certain in the practice of medicine of to-day it is this, that the poison of typhoid fever is not generated in the body *de novo*, but that it is introduced

from without, that it may be introduced in various ways by food or drink, or careless and uncleanly handling of the dejecta of patients, and that it is certain, just to the point of absolute proof, that the poison consists of a germ to which the name *typhoid bacillus* has been given.

I shall leave the discussion and demonstration of the bacillus to more competent hands, but will conclude with a few remarks connecting the doctrine of the microbic cause of typhoid fever with some clinical and pathological facts. It is impossible for us, even after the circle of evidence in support of the bacillar origin of the disease shall have been positively proven to dive down the stomach of a patient and follow the invasion of the bacilli thence onward. But let us, with such light as we possess, follow them in our imagination. We have a patient who has been drinking well-water or ice-water containing the bacillus or the spores (?). His stomach secretion is acid and does not form a favorable settling-place for the microbe. The out-flow of gastric secretion prevents it from finding a lodgment, as do the secretions from the upper portion of the small intestines, including the pancreatic and biliary secretion. In addition, the current of capillary circulation in the mucous follicles here is outward, rather than inward. But as the bacillus passes down into the ilium and cæcum, the current begins to flow inward rather than outward. The patient perhaps has, by some indiscretion in diet, contracted a slight intestinal catarrh, some little local lesion by fruit seeds, or what not, sufficient to abrade or denude, here and there, the upper epithelial covering. The bacillus finds a lodgment in one or the other solitary or agminated gland, and under the most favorable surroundings begins to develop and multiply. Gland after gland becomes involved; and, as the multiplication of bacilli and their spores (?) goes on, the lymphatics become involved and the bacilli are carried on into the general circulation. Up the lymphatic vessels into the thoracic duct, up the vena cava into the heart, through the lungs back to the left side of the heart, into the general circulation, down the abdominal aorta a short distance, when the great current of a large arterial stream carries them through the splenic artery into the spleen. Or, instead of being taken up into the thoracic duct, part may have been carried through the mesenteric glands into the mesenteric veins, and thus first through the portal circulation, there to encounter to some extent the germicidal effect of the bole, as those carried through the lungs are probably largely devitalized by the effect of oxygenation, but a portion are undoubtedly still carried on through the hepatic vein into the vena cava and onward as before until they reach the spleen.

The somewhat detailed allusion to the vascular arrangement of the spleen made above here finds its application. In the first three weeks of the invasion of the typhoid bacilli the spleen enlarges, swells up, sometimes to three or four times its natural size, undergoes a process of hyperplasia of its normal elements, and finally, with recovery, resumes its natural condition, leaving no trace of permanent lesions, except in rare instances. Is there a reason for this? Unfortunately the physiology of the spleen gives us no clue. Let us bear in mind these three facts: that the spleen is the receiver of a relatively large amount of blood which circulates in it with a great deal of sluggishness on account of the tortuosity of its arteries and glandular attachments; that in consequence of the arrangements of the veins and their connection with the portal system, this sluggishness of circulation is not counter-balanced, and lastly, that the spleen, as far as present investigations have resulted, is a favorite repository of the fever bacilli. Shall we look upon the splenic lesion then as simply accidental, or as one in the chain of reaction against the intruding microbes? With the clinical experiences in regard to other diseases of undoubted microbic origin —such as yellow fever, malarial fever, anthrax, etc., in all of which a similar enlargement of the spleen takes place, I have no hesitancy in saying that we have a right to attribute to this organ an active rôle in the series of processes of recovery from typhoid fever. The spleen, to use a homely illustration, is a sort of temporary guard-house, a prison for the transient confinement of the millions of invading poisonous tramps, where they may be either cleansed or starved to death, or experience a gradual jail-delivery, without an opportunity to overrun the commonwealth, and so are rendered comparatively harmless. The spleen I look upon as a trap, wherein the bacilli are caught.

Here speculation ceases and a new light dawns. The stellar worlds that Galileo dreamed of became visible to Herschel, and as the nebulæ are resolved by the great

Lick refractor into individual starry worlds, so speculative philosophy in medicine must submit to the inevitable and yield the sceptre that it swayed for centuries to the new science: to culture tube and Abbé condenser.

EDUCATION IN AMERICA.

BY SAMUEL G. DIXON, M. D.,

PROFESSOR OF HYGIENE IN THE UNIVERSITY OF PENNSYLVANIA.

There is probably no more difficult problem to solve than that of education. It is claimed by some that we have brought the standard up to a higher level than, perhaps, any other country, excepting Germany. But in doing this, have we thoroughly comprehended and grasped the meaning of the word; or, in other words, have we realized all that is meant by it? We may have sent out from our universities, young men thoroughly equipped in their various branches of science or commercial training; able to take their places at the desk, in the laboratory, the law courts or the forum, or at the bedside. But in doing this, have we fulfilled our whole duty to them? I fear not. Something is lacking. What is it?

The answer comes back to us in an ominous form. The records of our criminal courts, the almost daily reports of absconding clerks and defaulting cashiers, physicians convicted of malpractice, physicians accused of improper conduct in the sick-room, men in positions of trust suddenly disappearing, who previously held a high place in their community, who ranked high in the Church and enjoyed the regard and esteem of their neighbors, all these instances furnish us with a sad reply. And yet these men went forth into the world thoroughly trained and competent to perform the duties of their respective callings. Their intellectual training was complete, but something was wanting. What was it? I think the answer simple. There was no moral stamina, and when the hour of temptation came, they simply succumbed and fell down like a house of cards.

That the danger is a great one to our community is not to be questioned—it is open and palpable. How can we counteract it or in other words, how can we with our educational system provide at one and the same time for the moral and intellectual training of the mind? The latter is abundantly provided for, the former is very generally ignored. Home training and home influence are relied upon to afford what our universities fail to supply. These may be good, bad or indifferent, but if they are bad, there is nothing to put in their place.

The most critical period in the life of a boy is when the time comes to go to college or university. He has to rely much on his own resources; and, if his nature be weak and wavering, a hair's breadth may turn it for good or evil. The education of the mind begins at the cradle and ends with the grave. Mr. Gladstone, a few years ago, learned Italian in order to master Dante; but I believe the training of the moral faculties is practically ended at manhood. Impressions formed during childhood and adolescence are indelible, and I firmly believe that the moral impressions received during the first twenty years of a boy's life will ultimately guide him in after life. They may become strengthened and solidified as years go by, but they will not deviate much from the early path.

This brings me to the point I most strongly wish to urge, namely, the great necessity of a high moral tone among those whose duty it is to complete the educations of young men soon to enter into life. To educate we must strive to unfold the higher faculties of our natures; to succeed in this with others we must exhibit such virtues. The university or college student is naturally inclined to look upon his teacher as a model. It is an undeniable fact that tutors frequently indelibly stamp their characteristics upon their students. The leader of any educational institution should be qualified to instil those great principles of moral self-government which lie at the root of every well-regulated character.

In this connection we cannot but call to mind the example of Dr. D. Hayes Agnew, whose life and work will ever stand out as a beacon in the history of medical and moral education. Many of his students were his personal friends and their extraordinary attachment to him was owing to the great moral influence he exercised over them.

Moral and intellectual training must go together, hand in hand. The example must be real, and must consist in the highest performances of the duties of life. But there is a spurious imitation very prevalent, which palms itself off as the genuine thing, about

which I would like to say a word before concluding. Let me illustrate my meaning. Our doctor comes to me and says: "My dear sir, you are killing yourself by excessive drinking, and unless you make up your mind to stop it, you will ruin your constitution and come to an early grave."

We think it over and arrive at the same conclusion and determine to give up drink in order to lengthen our days, and the better to enjoy life. We plume ourselves on having done a meritorious action and receive the congratulations of our friends with much self-complacency. Now if we come to analyze it, this is not a moral act in any sense of the word. We have acted not by the light of any principle of ethics, but simply from an interested motive and an instinct of self-preservation.

But if the doctor says "I earnestly want you to give up drinking, not only because it is impairing your mind and warping your moral nature, but also because it is inflicting a grievous injury on your wife and family, degrading your family name, and causing sorrow to those who love you." Then, if we decide to give up the evil habit, we are acting, not only on moral, but also on religious grounds, of the highest kind.

For the spurious morality we have no use —call it by its right name. It would send out into the world a breed of prigs, however highly cultivated. The real morality will give us a race of Christian gentlemen. It is this real morality that we must have among those entrusted to mold the minds of our young men.

Intellectual cultivation without a corresponding moral culture goes to increase the power of the possessor to execute the mandates of the Devil.

I have not space to pursue this important subject farther, but I trust I have said enough to show the vital importance of a high practical moral example by those connected with educational institutions and who have the oversight of young men and women about to take the first step into the perils and dangers of the world.

—By the light of bacteriological investigation, the problems of ventilation assume a new form, and in the ventilation of rooms we shall soon need to ask whether the greater danger lurks in the so-called impure air of such rooms, or in the germ-laden outside atmosphere which we admit as "pure."

PEROXIDE OF HYDROGEN.

BY CHARLES P. NOBLE, M. D.,
PHILADELPHIA.

The use of this agent in therapeutics by the profession in general has been limited, and the opinion expressed by many concerning its value has been uncertain, or certainly not laudatory. My own experience has convinced me that it is an agent of great value, hence this short communication. I was induced to use peroxide of hydrogen through the recommendation of an aurist who had employed it to cleanse the auditory canal. The first case in which I used it was one of syphilitic rupia. When first seen, the patient, a woman, was covered with sores and crusts, literally from the crown of her head to the soles of her feet. The physician preceding me—the eighth in attendance on the case—had used ointments as an external application. As a result, the woman was greasy from head to foot, her clothing and the bed being in like condition. It was during the heated term, and swarming flies completed as wretched a picture as I ever beheld. I was told that the patient could not be made to eat. And I could not wonder. Daily ablutions, with use of diluted peroxide of hydrogen, to clean the sores and to disintegrate the crusts, together with the application of subnitrate of bismuth as a drying powder, soon changed all this and the patient felt clean once more. This I am satisfied saved her life—she was at death's door—as the internal treatment employed by myself was doubtless the same as given by my predecessors. The sores healed kindly under this treatment with internal administration of ninety grains of iodide of potassium daily.

Since that time I have used freely the peroxide of hydrogen as a cleansing agent. I was especially pleased with its action in a case of fecal fistula, following the removal of a dermoid cyst of the ovary. This fistula was probably caused by the hair from the dermoid cyst having grown into the bowel. No fecal odor was noticed during the operation, but it appeared in the drainage-tube two days later. The amount of fecal discharge was small, but it, of course, infected the drainage-tube tract and excited pelvic peritonitis. The abdominal wall about the incision became brawny and slight sloughing resulted. The discharge was re-

moved from the tube with cotton, on the cotton forceps, and the tube and incision were cleaned with dilute peroxide of hydrogen several times daily. The patient—who was a brave girl—remarked that she had a soda-fountain inside her. And it was indeed remarkable to see the disintegrated discharges bubble out of the drainage-tube and incision. Corrosive sublimate solution was also used sparingly. By keeping the parts clean in this way, the fecal fistula closed after three weeks, and the incision healed excepting at the site of the drainage-tube. The sinus remaining gives no trouble and is fast closing up.

The peroxide has been equally satisfactory in disintegrating the pus in a number of cases of abcesses. No one can appreciate the difference in the cleanliness obtained by washing an abscess with water and that by the peroxide. I have recently used it to irrigate a pleural sac, after evacuating a pyo-pneumo-thorax by a free incision. In three days the stench from the discharge in this case was entirely controlled.

The peroxide had been used pure and dilute—as dilute as one part to six. I feel sure that the peroxide has a wide field of usefulness before it. As a harmless and efficient cleansing agent I know nothing to equal it.

CEPHALHEMATOMA OF THE NEW-BORN.

BY STANLEY M. WARD, M. D.,

SCRANTON, PA.

My experience with cephalhematoma has been somewhat unique, if I may judge by what the books say, and by what older physicians, and in some cases, those of large obstetric practice, have told me. Believing, therefore, with the great Chanceller, that every man is a "debtor to his profession," I submit a somewhat detailed account of that experience, at the risk of being criticized for my treatment, and perhaps, too, for my opinion.

No definition is required to explain the meaning of the word "cephalhematoma." Unlike many terms in medicine and other sciences, the term plainly expresses the condition present. Its cause is *sub judice* in a great measure. In the course of this communication an attempt will be made to explain why this is so.

It would seem quite evident to the casual observer that a soft fluctuating tumor on the presenting part of the head of a new-born child was simply the result of pressure, was a "bulge," in fact, of the soft tissues, produced by the other part of the head being squeezed by the uterus. Ellis, writing in 1878, says that it "is often the result of pressure from protracted labor." Other authorities pay little attention to the entire subject, and Ellis himself devotes only ten lines to it in his work, as found in Wood's Library. Parvin, in the *Cyclopædia of the Diseases of Children*, edited by Keating, passes it by as a matter of little consequence, as does also Henoch; so that I am constrained to believe that, by a large number of medical men, the view given above is generally accepted. On the other hand, Virchow gives an elaborate explanation which, if it be correct, stamps cephalhematoma as a diseased condition, the production of which is by no means so simple a matter as has been assumed. He says, "the pericranium grows by proliferation of the inner layers of the periosteum. If, then, the pericranium, through the blood which is poured out, is held apart from the cranium, the bone-producing layers of the periosteum being still thrown off, they cannot reach that part of the bone for which they are intended. Eager, however, to fulfil their office they join themselves to the bone at the border of the tumor where the bone is still attached." It must be evident to any one that Virchow was describing a tumor of far more consequence than a simple œdema or even a hematoma on a child's head. Besides, the tumor under consideration is not always on the presenting part, and has been known to occur in a breech presentation. Judging from the disparity of opinion among authorities as to its importance, and from my own experience, I believe there are two varieties of cephalhematoma: one variety situated between the periosteum and the cranial muscles, which is probably in all cases the result of pressure; the other is a more formidable affair, and is situated between the bone and the periosteum. This variety is, I believe, a matter of more consequence; is an evidence of a constitutional fault, and is never the result of pressure. It is, perhaps, best accounted for by Virchow's hypothesis, and, of course, may be found on almost any part of the child's head; may be double, and the presentation of the child

has nothing to do with it. It would seem as if some observers had mixed these forms and had classed the *caput succedeum* with them, and then concluded that the entire subject was of little consequence—that all tumors on new-born children's heads, excepting cranio-tabes, hernia cerebri and meningocele were only evidences of a hard and difficult passage into this world.

The frequency with which this tumor occurs is stated by McKee, in the Reference Hand-book of the Medical Sciences "to be, so far as can be learned from the statements of authors, 1 to 235 of children born." Dr. Charles Warrington Earle, of Chicago, in a somewhat recent publication, questions the accuracy of these statements, and says cephalhematoma occurs more often. This opinion I, too, hold; for in my personal practice and as an associate with Dr. J. J. Ward, of Ellensville, N. Y., eight cases have occurred. However, practitioners of large obstetric experience, covering ten or more years, have told me that this condition was unknown to them. As before indicated, cephalhematoma is divided into varieties according to the seat of the effusion. Dr. McKee, in the article referred to, says there are four. I do not think anything is gained practically by so many divisions; and I have given only two varieties. Dr. French, of Missouri, in an article which was very helpful to me, appearing in the *Archives of Pediatrics*, March, 1884, gives as varieties the sub-aponeurotic, and the sub-pericranial. I believe a better and more correct name for the second variety would be sub-periosteal. If it be true that the first-named variety is more of a local trouble and produced by local means, then it would follow that it would be, on the whole, the more common form, and, being present at birth, would reach its maximum growth a short time afterwards; while the opposite in every respect would be true of the last named. This happens, I think, in practice.

The diagnosis from other tumors affecting new-born children's heads presents few difficulties. "A soft, elastic, fluctuating tumor, generally painless and situated on one of the cranial bones" (Earle), which, unless exceedingly large, is not particularly noticeable until from eighteen to twenty-four hours after birth and which is surrounded at its base by a ridge of bone—"nature's efforts to repair the injury" (Earle)—is not likely to be mistaken for anything else. The differences existing between the two varieties are the appearance of the sub-aponeurotic form on the presenting part; its great size as compared with the other form; the irregularity of the ridge of bone surrounding it—not always readily found; its irregular form; with its tendency to spread and the discoloration of the skin covering it. Dr. French insists on these and other diagnostic points, and on one other which is perhaps of more practical importance than any of the others, namely, that the sub-aponeurotic—the local form, so to speak—tends to slowly diminish after a week or so, and will usually disappear without treatment in two or three weeks.

Nearly every writer consulted by me recommends the let-alone treatment of cephalhematoma. I think in some instances this is due to the failure to distinguish the different varieties and to confound the tumor with the *caput succedaneum*. This last-named tumor and the sub-aponeurotic form of cephalhematoma will in the great majority of cases disappear with or without discutient lotions, pressure, etc. But I have waited in a case of the other variety over three weeks, using this treatment, with no result. There was not the slightest evidence that the tumor was diminishing. This case had the following history: A male child was born of healthy Irish parents. The mother was a primipara, and an exceedingly large, muscular woman, accustomed all her life to hard manual work. The labor was tedious, but was finally terminated without instruments. On the second day a tumor was discovered on the right parietal bone. It was diagnosticated as a tumor not connected with uterine pressure, but we were ignorant of its exact nature, it being the first one of the kind that the attending physician, Dr. J. J. Ward, or I had ever seen. The author and an elderly practitioner of a large experience, saw it during the second week and failed to diagnosticate it. Treatment with lotions, etc., had been faithfully carried out, with no result. It seemed as if the tumor grew every day; but this is questionable. At the end of three weeks it was as large as a fair-sized orange, regular in shape, and the bony margin was well marked. Yielding to the solicitation of parents, the attending physician, assisted by myself, opened it at the base with a lance. The blood flowed freely, the tumor diminishing in size. The wound was dressed antiseptically, absorbent cotton being used, and a bandage was placed over all. The next day the dressings were soaked with blood, the tumor was nearly as large as

before, and the child was very pale. After renewing the dressings a probe was inserted into the cut to break up possible adhesions, and the dressing was renewed. Twice daily did we dress the wound for a week thereafter, the child in the meantime becoming very weak and anemic; indeed so exsanguinated was he that doubts of his recovery were freely expressed. Finally, two weeks or more having passed, there was no more hemorrhage, and the entire tumor disappeared. The child recovered rapidly, and is now healthy and strong. I think the mistake in this case was, either in not opening the tumor sooner, or if it was deemed necessary to empty it, that we did not use an aspirator, instead of the lance, though then, because of the thickened blood, much trouble would have ensued. In seven more cases—one double—the treatment sketched above has been carried out, but with no such trouble and anxiety. The lance was used in every case at a date varying from the sixth to the twelfth day. In every case but one, the history of which follows, no untoward result followed.

That all these tumors were cephalhematomata admits of little doubt, as the first case was studied very thoroughly, it being an anomaly to all concerned. Again, though no doubt as to the nature of the tumor existed, in order to make assurance doubly sure, in no case was the operation done before the sixth day, and usually it was done later. Any other tumor, except those rare and serious forms about which a mistake is not likely to be made, would have disappeared before that time. Several of the cases were the more common and the less serious cephalhematoma sub-aponeurotica, appeared on the presenting part and had the ridge of bone imperfect. In some cases the covering of the tumor was discolored; in some, even of the sub-aponeurotic form, it was not. In all the same treatment was carried out, as we deemed it innocuous, and as it is very gratifying in its results to the anxious mother who wishes her child to be in a presentable condition at least by the end of the second week. My last case is as follows:

November 26, 1889, I was called to see a German woman, who had been attended in her confinement some days before by a midwife. I found her in a condition of sepsis, produced evidently by the uncleanness of the lacerated external genitals. On the occasion of my fourth or fifth visit, my attention was drawn to the child by the midwife. On examination, I found a male child, to all appearance healthy and well developed; but, occupying the lower part of the right parietal bone, was a tumor. The midwife said she had not noticed it at the child's birth. All the characteristics of a sub-periosteal cephalhematoma were present, and I so diagnosticated it. The next day, the child being twelve (12) days old, I lanced the tumor at its base. A quantity of blood, not enough to hurt the child—which indeed hardly waked from its sleep—came slowly from the cut, and the tumor diminished by degrees. On the next day the child was not feeling well. It was cross and irritable. Some blood had oozed out during the night; but the tumor was about one-quarter its original size. With a probe I opened the wound and carefully pressed out the blood, and dressed the wound with absorbent cotton and applied pressure. On the following day the tumor was gone, but the child was in a bad condition, was listless and inclined to sleep. When roused he moaned and cried a little. Ecchymotic spots now appeared over one side of his face, and part of the chest and the scrotum were greatly enlarged and reddened. In fact, many symptoms of purpura hemorrhagica were present. Two days afterwards he died of exhaustion and inanition. I am not certain that my interference had anything to do with the death; but, if I had never operated before, such an opinion would have appeared very probable to me. It will be noticed that the disaster was not such as the advocates of the "let alone" treatment state will follow interference, at least so far as I know.

These two cases are the only ones of the eight that presented any features worth commenting on. Reasoning from experience and from what we know of the pathology of these tumors I believe, in spite of what many authorities say, that to make a free incision at their base; to gently press them; and finally to dress them with boiled water, applied freely; and to cover them with a roller bandage, is good treatment. Even if convinced that a given tumor is an example of the simplest form—the sub-aponeurotic—if after pressure moderately applied, it should show no signs of disappearance at the end of a week or ten days, I believe the good of the child, certainly the comfort of the mother, would be best secured by the operation described. I think in some cases aspiration would be safer; bulas before sug-

gested, on account of the thickened condition of the blood, especially after the second week, much difficulty would be experienced.

CONSUMPTION RETARDED, IF NOT CURED, BY AN ACCIDENT.

BY JOHN B. CRANDALL, M. D.,
STERLING, ILL.

Mrs. Henry Thomas, 62 years old, a resident of Sterling, was in the second stage of tubercular consumption; had great emaciation, with severe cough, night-sweats, hectic chills, and all the other rational symptoms. This state of affairs was progressing when she met with an accident. She slipped on the sidewalk and fell down, fracturing the right femur. Upon examination, I found introcapsular fracture of the right femur. Mrs. T. was in such a deplorable condition generally I did not put the limb in splints but had an adjustable leather support to steady the limb, so that she could sit up in bed, in order to ease the severe strain and cough. She progressed as well as any case could, so far as the treatment for fracture was concerned. As soon as the deposit of callus on the fractured bone commenced there was marked improvement in her cough, she ceased to have hectic chills, the expectoration became less, and was less tenacious in character, and her general health improved. She gained in weight, and all the symptoms of lung disease were checked.

This coincidence happened more than ten years ago; and the woman has been up and about since, with no recurrence of lung trouble.

In this case, as soon as the deposit of bone began to be thrown out there was a marked improvement in all of the pulmonary symptoms. Whether or not this fact indicates a line of treatment for tubercular phthisis I leave for the philosophers in the profession to determine.

SANTONIN.—The competition among the Russian santonin-makers has continued throughout the past year, and this has led the Chim Kent works again to reduce their price for the article by 25 per cent. The present quotation excludes the possibility of manufacturing santonin profitably in Germany.

REPORTS OF CLINICS.

PRESBYTERIAN DISPENSARY, CHINANFU, CHINA.

SERVICE OF DR. ROBERT COLTMAN, JR.

Leucoma.

This little girl is twelve years old. At three she was attacked by small-pox in the confluent form, and she is badly pox-marked; but the disease did more than destroy her good looks: it has robbed her of her eyesight. The right eye has suffered most, and is hopeless from straphyloma and a leucomatous cornea. The left eye is almost hopeless, also due to leucoma; but, as there is a clear space of cornea just at its outer margin, I propose to perform an iridectomy, in hope of obtaining at least partial sight. I nearly always use a Beer's knife for the incision of the cornea, and shall do so here. I draw the iris out through this incision, and clip off a good-sized piece close to the cornea. In this case a very large false pupil will do no harm, as it cannot be seen, and a small one might not be sufficient. You observe that the iris remains caught in the lips of the wound. It is important to replace it before it becomes attached in its present position, which it would be sure to do. For this purpose I use the iris forceps, simply pushing the incised surface back into the anterior chamber. The instillation of two drops of an atropia solution (one grain to a fluidounce of water) completes our present treatment of her case. Her eyes we will keep closed for two days, when we shall see her again. I fear the result will be poor, as the cornea has such a very slight area unclouded; but in her desperate condition even a little sight will be a boon.

Psoriasis Capitis.

This boy is fifteen years old. His head looks as if he had a white night-cap on, and his hair has nearly disappeared. This is an unusually bad case of psoriasis capitis. In some places you see large white scales collected into little heaps or hills; these are called "rupioides." When I first came to China I experimented with a number of remedies for the cure of this complaint, with very little success; but now the cases uniformly recover in a very short time. My treatment is: wash thoroughly in warm water each morning; then wipe entirely

dry, and anoint with an ointment composed of equal parts of pix liquida, oleate of mercury (five per cent.) and cosmoline. Internally I give ten-drop doses of syr. ferri iodidi after each meal. We will put this lad upon this treatment, and direct him to return in five days, when I promise you he will present a different appearance. As for the loss of hair, I fear it is permanent. In some of the milder cases the hair follicle does not die, but lies quiescent; and, when the disease is removed, again sprouts a hair; but in a case as severe as the present one the disease is deep-seated and has probably destroyed the hair follicle.

Pterygium.

This man, a farmer, fifty-three years old, comes to us for an operation the second time. You will remember that I operated on him for pterygium a month ago, and, after dissecting back the growth, made a small incision in the conjunctiva at the margin of the lower lid, and, diverting the end of the growth into this incision, fixed it there by one point of suture. This is called transplanting, and is by long odds the best way of treating these cases. But this man, in spite of my injunctions, kept wiping his eyes with a coarse cotton handkerchief, and soon tore out the point of suture, allowing the growth to become free and unattached. This has grown in thickness, and worries him, as it flaps back and forth as he rotates his eyes. I shall simply dissect it back to the inner canthus, excise it, and then touch the stump and bleeding surface with a piece of copper sulphate. This will give him relief for some time, but in a period of from six months to three years the entire growth will probably be reproduced, and will necessitate the transplanting operation again.

Chronic Diarrhœa.

This man, fifty-three years old, is an officer in the Civil Service. He says that three years ago he caught cold near the sea-coast, and that a diarrhœa followed, and has kept up until the present day. At first he had four stools a day; then more; and now he has ten in twenty-four hours, and also some blood in them. The fact that he has very little pain is probably accounted for by the fact that he takes two drachms of opium daily. He is anemic, and somewhat jaundiced. His liver is somewhat enlarged; his heart, lungs and spleen are normal. I find —no matter what is the trouble with an opium-eater—that quinine, or some salt of cinchona, is an important adjunct to the treatment; so I shall prescribe for this man the following:

℞ Cupri sulphatis . . . . . gr. ss
Quiniæ sulphatis . . . . . gr. xii
Ext. taraxici . . . . . gr. xii
M. Ft. pill No. vi.
Sig: One pill three times daily.

He will report at the end of two days. This patient will probably be hard to cure. He will do well for a time, but will relapse because of indiscretions in diet. I shall order him to abstain from everything in the way of food, excepting soft boiled rice and warm milk. He will certainly improve steadily for a time; and he will as certainly add other articles to his diet before he has permission, and delay, if not prevent, his recovery.

Scabies.

This is a sorry-looking group: father, mother, boy, girl and baby. It is not often that all the members of a family have the same complaint, but when it does occur it is probably—as in this instance—the itch. You will notice that the mother, who is the cleanest looking of the lot, has the affection in the lightest degree; while the boy, who is extremely dirty, is a mass of sores.

Itch is always more common at the end of winter, because people crowd together more during cold weather, and wash less. We will suggest to this group of patients that they take a bath, and then anoint themselves with an ointment of two drachms of sublimed sulphur to an ounce of cosmoline. Several repetitions of this process will ensure a cure.

Sugar of Milk.—The fine recrystallized varieties of sugar of milk produced in Northern Germany have been very scarce, while the supply from Switzerland has been forthcoming on a somewhat more liberal scale. The strong demand from the United States for both varieties continues, notwithstanding that there are now facilities existing in the States for the wholesale production of sugar of milk. It is said, however, that neither the grape form nor the crystallized variety of sugar of milk is made in the States, but only a rather unsatisfactory powdered product, which would scarcely be suitable for homœopathic purposes, although it has a very large sale in America.

FOREIGN CORRESPONDENCE.

LETTER FROM PARIS.

Erysipelatous Broncho-Pneumonia without Erysipelas of the Cutaneous Surface.—Treatment of Fractures of the Patella by the Extensive Opening of the Knee-Joint. Excision of the Transverse Process of the Seventh Cervical Vertebra, for Compression of the Bronchial Plexus.—Treatment of Hydarthrous of the Knee.—Surgical Treatment of Club-foot.—The Mixed Diet for Infants at the Paris Maternity.—Treatment of Anthrax.

Dr. Mosny recently presented to the Academy of Medicine of Paris some interesting observations on erysipelatous broncho-pneumonia. This location of erysipelas has been denied for a very long time. In 1879, Dr. Strauss recorded a case of this description, and during the recent epidemic Dr. Mosny came across the following case:

A servant girl who was nursing her master, suffering with facial erysipelas, was taken with pneumonia and died two days later. At the *post-mortem* examination, there was found a very limited area presenting the characteristic appearances of broncho-pneumonia. Bacteriological tests and cultures showed the development of characteristic colonies of the streptococcus of erysipelas, without the admixture of any other micro-organisms; and inoculations have, moreover, demonstrated that this streptococcus was identical, as to its effects, to the streptococcus of erysipelas. The conclusion is that this case was a primary erysipelatous broncho-pneumonia, having not been preceded by any cutaneous or mucous manifestations of erysipelas, nor by any streptococci suppuration.

Dr. Lucas Championnière also presented to the Academy the results of fourteen cases of fractures of the patella which he has treated with the metallic sutures. When the operations were performed immediately after the injury, that is, within the twenty-four hours, the results were much more favorable. The operator opens the knee-joint very broadly, washes it out very carefully, and under the most antiseptic rules, he removes any splinters of bone which may be present, and finally sutures the bone, the patella, by means of very strong silver sutures; two of these, being passed through its substance, are sufficient. Drainage-tubes are inserted so as to enable the neighboring parts of the articulation, which are the seat of effusions, to empty themselves. The limb is then placed, for a period of eight days, in a wire splint, and a simple dressing applied. Never is the articulation rendered absolutely immovable, Dr. Championnière insists on this point. At the end of from twenty to twenty-five days the patient is allowed to begin to walk, when osseous union is already established, as one is unable to find the line of fracture of the bone.

When the operation is performed by any of the several other methods usually employed, the result is not so good; out of five cases, in two cases only did he obtain perfect union between the fragments; in the other, he was unable to bring the fragments close to each other and so he left the silver sutures in position and they gave no trouble.

Dr. Périer presented an interesting case of the excision of the transverse process of the seventh cervical vertebra. The patient, a young man, had been suffering for many years with severe pains in his right arm, accompanied by a very marked atrophy of the same extremity; while at the same time his voice was very much interfered with, which seemed to indicate serious lesions in the laryngeal region.

Upon physical examination a very apparent projection on the right side, above the clavicle, was found, also one on the left side, but less prominent; and the whole neck was enlarged. These projections were the transverse processes of the seventh cervical vertebra, the right one being very much developed; and on a level with it, one could feel the beating of the subclavian artery. The brachial plexus, which was displaced, is also compressed, which accounts for the severe pains, the muscular atrophy, the alteration of the voice due to the compression of the recurrent nerve. The operation was a difficult one, the transverse process was excised, and during this operation the plural cavity was opened, but this accident, after having determined, on the following day, a severe dyspnœa and a sub-cutaneous emphysema developed on account of the introduction of air into this serous cavity, but this disappeared in a few days. The patient was then subjected to electricity, gymnastics, douches, etc., and since then his arm has completely recovered its use, the pains have

disappeared, and the voice has become normal again.

At the Societé de Chirurgie, Dr. Terrillon spoke on the treatment of hydarthrosis of the knee (effusion in the joint), by means of aspiration, and subsequent injections of carbolic acid solution. He presented a young woman, whose knee he had aspirated, and had obtained six hundred grammes of liquid from the joint. The case was one of hydarthrosis of six years' duration, which had rendered the patient absolutely incapable of walking. Five syringefuls of strong carbolic acid solution were injected, altogether 1,300 grammes, to wash out the cavity; and compression was then applied. The patient was discharged as cured at the end of a month. One year after the operation, there was still a little liquid in the joint, but the patient now walks perfectly well.

At the same society, Dr. Lucas Championnière spoke on the treatment of club-foot by extensive excision of the tarsal bones. The principal part of the operation consists in the bony destruction, and especially the extirpation of the astragalus, followed by section of the tendon Achilles. The excision of bones must be sufficient to bring on a complete correction of the deformity. There is no objection in taking away as much bone as necessary, and in one case the author had excised the astragalus, the scaphoid, part of the cuneiform and the cuboid and calcaneum. As to the cutting of the ligaments, they are not of great importance; and the only bone that must not be removed is the external malleolus.

After extensive excisions, the foot is so firm that a containing apparatus is hardly necessary; hence a large removal of both soft and bony parts is to be recommended; moreover, an extensive bony excision greatly helps the union of the soft parts after the operation, and this immediate union is very important for the success of the operation, for we must not rely upon consecutive treatment to complete the reduction; this must be immediately obtained and by operation. The wound heals after one or two antiseptic dressings; the movements of the foot must be commenced early; the patient should be able to walk well at the end of six weeks. At first, Dr. Championnière recommends a boot with lateral splints, to prevent lateral movements and sprains, but later the boot is hardly necessary. Out of eight cases, he has had six perfect successes; the seventh was very slow in walking; and the eighth resulted poorly, which he attributes entirely to not having excised enough bony tissue.

Dr. Berger, out of six cases, has had four attended with perfect results. The two resulting imperfectly were cases where the bony resection had been very limited; while in the four successful ones, the bony excision had been a very extensive one. Dr. Berger insists upon not using drainage and only applies one dressing between the fifteenth and twenty-first day. A plaster-of-Paris splint is placed immediately over large cotton dressings. His patients begin to walk in four and five weeks; later they wear boots but without lateral splints.

At the Paris Maternity, Madame Henry, the midwife-in-chief, gives a mixed diet to infants in the following manner.

The mixed diet is the one to be recommended when a mother is unable to furnish enough milk to her child on account of insufficient secretion; or again, when the financial position of the mother prevents her from keeping a nurse in the house; this mixed diet consists in feeding by the breast in addition to other food. At the Maternity, the hours of feeding are as follows:

8 A. M.—Breast feeding.

11 A. M.—Breast feeding.

1 P. M.—Milk or equal parts of milk and distilled water.

3 P. M.—Breast feeding.

5 P. M.—Milk or equal parts of milk and distilled water.

8 P. M.—Breast feeding.

11 P. M.—Breast feeding.

1 A. M.—Milk or equal parts of milk and distilled water.

3 A. M.—Breast feeding.

5 A. M.—Milk or equal parts of milk and distilled water.

The mixture of equal parts milk and distilled water may be replaced by gruel containing 3 per cent. of sugar of milk.

The milk must always be boiled.

If diarrhœa appears, Madame Henry prescribes the following mixture:

Rum	3 teaspoonfuls.
Water	1 tumblerful.

M. Sig.: Give three or four teaspoonfuls in the twenty-four hours.

If this is not sufficient, the following prescription is used:

℞	Napthol B	gr. j
	Water	f℥jx

M. Sig.: Two or three teaspoonfuls in 24 hours.

Dr. Polaillon, of Paris, treats anthrax, which he considers an essentially microbic disease, by destroying the centre of the lesion; he prefers to the use of the knife, Paquelin's thermo-cautery, or better still, Canquoin's paste (chloride of zinc, ℥jss, wheat flour, ℥jss, water, q. s.) made into a cone and introduced into the tumor, through the suppurating channels. In a few hours the core of the anthrax forms a solid mass, which is separated from the healthy tissues by cauterized tissue, and in a few days the eschar is eliminated, leaving a granulating surface, which heals very rapidly. When the anthrax begins, and there is no existing suppuration, he uses compression and poultices on which a carbolic acid solution or bichloride solution has been placed, using antiseptic water to make the poultice. This treatment is painful to the patient for one, two or three hours, but it rapidly breaks down fever and all other alarming symptoms. Out of 75 cases of anthrax, some of them very large, Dr. Palaillon has obtained 74 cures by cauterization by means of the cones of chloride of zinc. The average duration of the treatment is about twenty-one days.

LETTER FROM LONDON.

Specialists and Abuse of Hospitals.—Signor Zucci.—Prevention of Ophthalmia in Schools.—Dr. Savage on General Paralysis of the Insane.

London, April 5, 1890.

The Easter holidays have fallen in the midst of mild and lovely weather, and the Registrar-General's returns have already shown a sharp fall in respiratory diseases. Still, in a climate like that of Britain, where snows are not unknown in May, one can never be quite sure that the warm weather has come for good. All the world is now flocking to London. The next few months will bring in the harvest of the specialists, who have a comparatively quiet time of it during the winter: at any rate so far as their consulting rooms are concerned. There is never any lack of patients in the special departments of the hospitals; indeed, the complaint is all the other way, that out-patient departments generally are unwieldy and filled by an ever-increasing crowd of applicants for relief.

This question of hospital abuses has at length forced itself upon public attention, and the agitation for reform is assuming more definite lines of action. In the House of Lords it was officially stated that Government would not be averse to the appointment of a Royal Commission of Enquiry into the administration of public charities. The provinces have taken up the subject vigorously. In Birmingham, for instance, the Mayor has formed a committee of investigation having a judge for its chairman; and much discussion has been carried on in the newspapers of that town. In Liverpool the reformers have been especially active, and have issued numberless schemes and resolutions. Then the Charity Organization Society—here, as in America—well-nigh buried beneath the caustic comment that so much of its time was spent on organizing as to leave none for charity, seems to have taken a fresh lease of life, and has convened a large meeting to consider the audit and preparation of accounts of charitable institutions. All these signs of the times show that the question has thoroughly awakened public interest. General practitioners, who have long clamored for reform, will now have to prove their case, and the fear is openly expressed in certain quarters that exact evidence will not be forthcoming. It is one thing to say that well-to-do people get their advice and medicine gratis, but quite another to bring forward clear and formal proof of that assertion. Anyway, it may be confidently hoped that the matter will not be allowed to drop out of sight before being pushed to a satisfactory conclusion. Many people look to an extension of Poor-Law medical relief for a solution of the difficulty, and such a course would be quite in accordance with the modern tendency to apply the rules of political economy to social problems.

Among the holiday sights is Signor Zucci, the fasting man, on view at the Aquarium. He is pledged to fast for sixty days, taking nothing during that time beyond water and an "elixir" of his own composition, which contains no nutriment, but is intended simply to allay the pangs of hunger. His proceedings are carefully watched night and day by a body of journalists and medical men. Among the latter are several residents from the Westminster Hospital, which, as every one knows, is close to the Aquarium. The gentlemen who have thus allowed scientific zeal to outrun their discretion have got well "hauled over the coals" both by the hospital management and by the

medical journals, apparently on the following grounds : Although it is possible that fresh light may be thrown on the chemistry of starvation, and that some value may attach to the fixing of more exact dates of survival, yet hospital officials, on the score of such doubtful benefits, cannot be allowed to play, however unwittingly, into the hands of advertising speculators. Besides, the fasting game has long had its *coup de grâce*. One journal pithily remarks that there are plenty of starving men to be seen any day without paying a shilling a head for the sight.

The personalty of the late Sir William Gull has been sworn under £350,000. There is, in addition, a large real estate, bringing up the total sum to very big figures. As may readily be imagined, the bulk of this vast fortune was acquired outside the practice of the profession. The singular absence of charitable bequests has been made the subject of comment in some of the medical papers.

An interesting advance has been made in the treatment of ophthalmia in pauper schools. The Central London District has an extensive educational institution in the outlying suburb of Hanwell. Ever since the foundation of the school—now more than twenty years ago—there has been repeated outbreaks of the disease, which have never been altogether absent from the place. During that prolonged period reports have been made by experts from time to time, strongly condemnatory of the buildings and also of the methods of treatment. Towards the end of last year the matter was taken up warmly by the press, both lay and medical, and it was also made the subject of Parliamentary comment. The history of these proceedings—the twenty years' delay, the slow ripening of opinion, the leverage of the newspapers, and the question in the House, together present a typical picture of how things of that sort are done in England. Slow and steady are the ways of John Bull. However, the Hanwell managers at length took the decisive step of appointing Mr. Sydney Stephenson, an eye-surgeon who had before stamped out an epidemic of a similar nature at West Norwood, to the sole charge of ophthalmic cases. The next requirement was the erection of new buildings. This has now been done at a cost of £30,000 —a mere trifle when one reflects that the ratable value of the City of London, which along with the parish of St. Saviour's, Southwark, makes up the Central District, is no less than four millions sterling. Details of construction have been arranged in accordance with modern knowledge. Although scientific men have not proved the exact causation of ophthalmia, yet it is an accepted axiom that isolation, prolonged and thorough, is a *sine quâ non* of its successful treatment. In isolation, therefore, lies the key to the new buildings. Washing is on the "jet" system, by which each patient washes in a separate stream of running water. The baths are of spray, turned on by the child's weight ; a plan that reduces the risks of infection and saves water. The most novel feature, however, lies in the fact that isolation, medical treatment, and schooling will be carried on at one and the same time. This is the first departure of the kind in England, although the plan has been tried elsewhere. There can be little doubt that enlightened measures of this kind will eventually banish all existing cases and future epidemics of this pestilent scourge from pauper schools.

Dr. Savage has lately read a valuable paper before the Harveian Society on the warnings of general paralysis of the insane. He regards the malady as a degeneration rather than a specific disease. Speaking broadly, the slave has acquired, with freedom, general paralysis ; which, to put it in other words, is a disease of civilization, in direct ratio to the high-pressure life of cities. It is often very difficult to distinguish between causes and early symptoms ; for while drink, extravagance, restlessness, and sexual excess may, one or all, start the degeneration, they may, on the other hand, simply show loss of self-control. The bearing of early motor changes, such as fatigue and resulting indecision is pointed out ; and of ataxic changes with muscular defects of the hands and tongue, blurring of the features, aphasia and altered handwriting. Sensory warnings include neuralgia, sciatica, headaches and rheumatic pains ; with defects of special senses. Among intellectual changes are : want of social accommodation and such faults as stupid stealing and thoughtless indecency. And the curious point is that patients get drunk easily, and cannot resist poisons.

D. W.

—Tinned cherries have given rise to symptoms of poisoning, which Dr. A. P. Luff and Mr. G. H. Metcalfe have traced to the presence of malate of tin.

PERISCOPE.

Prejudices about Foods.

In his address before the Chemical Society of Washington last January, Mr. Edgar Richards called attention to the objections some people have to food liked by others.

A large proportion of the articles suitable for food and produced in all countries, he said, is wasted annually because of people's prejudice against them. The old saws, "What is one man's meat is another man's poison," and "There is no accounting for taste," are trite, but warranted by the facts. We do not object to eating a live oyster, but prefer all our other meats dead, and undergoing putrefaction to a slight extent, in order to get rid of the "toughness," as it is generally called, produced by the *rigor mortis*. Some people like to let the putrefaction proceed further until the meat is "gamey." The Texan cowboy eats goat's meat in preference to that of the cattle and sheep he is herding. Young puppies, rats, and bird's nests are considered delicacies by the Chinese. Frog's legs and snails are among the highest priced dishes served at Delmonico's. Except the bones and hide, every part of an animal slaughtered for food is eaten by most civilized nations—the brain; tongue; blood in the shape of black pudding and sausages; the liver; heart; lungs; stomach as tripe; the pancreas, thyroid and sublingual glands, which are called sweetbreads, and considered a great delicacy; the feet in the way of jellies, and pickled; the intestines as sausage covering, etc. In the markets of Paris there is a steady demand for horse-flesh as food. The Arabs and other nomadic tribes prefer mare's or camel's to cow's milk. Many people would as soon eat a snake as an eel, yet the latter commands a higher price than most fish in many parts of the world. Lobsters, which are the scavengers of the sea, are eaten by people who would not touch pork. The Eskimo, who eats blubber and other solid fats, and the native of the tropics, who "butters" his bread with a liquid vegetable oil, have the same object in view: viz., to supply a concentrated form of fuel. The squirrel is considered a great delicacy in many parts of this country, but is not eaten in England. The vain efforts of Professor Riley some years ago to induce the starving people of Kansas to eat the food they had at their doors—grasshoppers, sorghum, and millet seeds, and squirrels—himself setting them the example, will be recalled by many present.—*Science*, Feb. 7, 1890.

Damage by Disinfection with Sulphur.

Dr. H. R. Carter, of the U. S. Marine Hospital Service, writes to the *Journal of the American Medical Association*, April 5, 1890, that it is well to know that sulphur burnt in the presence of moisture may have the following undesirable effects: It injures the colors of many woolen goods, being especially hard on greens and bright reds—a red flannel shirt, for instance, always comes out yellow, sometimes the color is not affected; the dark blues are generally absolutely uninjured, but not rarely turned a reddish brown. The same color, of course, may be from very different dyes and thus give different results. The quality of the dye, as judged by the price of the fabric, is no criterion of how it will behave under sulphur. Clothes that have been worn are frequently discolored, when new ones, of the same nature, from the slop chest are but little or not at all affected, doubtless protected by the oil used in weaving, which has not worn off. Dr. Carter has seen but few colored goods, other than woolen, submitted to sulphurous acid gas; in some instances they were bleached.

Articles containing starch, if not washed soon, are corroded—this is especially true of handkerchiefs, etc., and the cloth covers of books. Blankets and hair pillows, which are utterly unsuited to the process—will retain for about a week a smell so disagreeable, in no sense like that of burning sulphur, that they are unpleasant to use. This persists in spite of airing and exposure to the sun, but is immediately removed by washing, or heating in an oven.

Flour in ordinary barrels will not "rise" with yeast for some days after exposure, and this effect penetrates for a considerable distance in the barrel. Tea is ruined permanently, as is ground coffee. The same charge is made of its effect on smoking tobacco.

All metal-work, all save gold, is tarnished, with consequent injury to watches, clocks, etc. Oil prevents this almost entirely. Apples and other fruit become scalded and worthless.

The gas in Dr. Carter's observations was obtained by burning as much sulphur as

possible in the presence of abundant moisture in a compartment more or less close, kept closed for from twenty-four to forty-eight and occasionally seventy-two hours. In general it was not possible to enter the compartment for some time—thirty minutes to an hour—after opening up. Where the apartment is more open less injury would be done and also less efficient disinfection.

Detection of Tubercle Bacilli.

The *Deutsche Medizinal Zeitung*, March 27, 1889, cites the following method for the detection of tubercle bacilli, as devised by Bliesener and described in the *Centralblatt für Bakteriologie*. The sputum is allowed to dry on a microscope cover-glass, and is then passed three times through an alcohol flame. The glass is then laid, with the specimen side up, upon a small tin plate about an inch and one-half square which is fastened to a support about six or seven inches high. With a pipette five or six drops of Ziehl's carbal fuchsin are placed upon the glass, and then the tin is warmed over the flame until first bubbles appear. The flame is now removed, and after a minute the glass is washed with water, and the cover-glass is allowed to float for fifty seconds upon a staining fluid made of

Methylene blue	1.5 parts
Distilled water	100.0 "
Sulphuric acid	25.0 "

After this the specimen is washed with water and is ready to be examined under the microscope.

The Vesicoscope a Source of Error.

A remarkable instance of the way in which even the most skilled are liable to be mistaken in drawing conclusions from physical signs was given in a paper read last week by Mr. Mayo Robson, of Leeds, at the British Gynæcological Society. The urine of a woman who had long been ill was found to be constantly loaded with pus, which, by means of the vesicoscope, was ascertained to come from the left ureter. On the strength of this apparently conclusive indication pyonephrosis was diagnosed, and the kidney was accordingly cut down upon. To the surprise of everybody concerned, this organ was recognized to be perfectly healthy, and a subsequent operation proved that the source of the purulent discharge was a pelvic abscess, which had established a fistulous communication with the left ureter. It is satisfactory to have to report that relief was ultimately afforded, and cicatrization of the abscess cavity obtained.—*Medical Press and Circular*, March 19, 1890.

Hypnal.

Hypnal is a new hypnotic remedy as its name indicates. It is a trichloracetyl, and its full name is dimethylphenylpyrazolon. The drug is obtained by the action of chloral upon antipyrin. It possesses the hypnotic and sedative properties of both its constituents. At the meeting of the Société de Thèrapeutique of Paris, held March 12, and reported in the *Progrès Médical*, March 22, 1890, Dr. Bardet read an account of his experiences with the drug. He gave hypnal in fifteen-grain doses. In twenty-two cases of insomnia sleep was easily induced. Excellent results were obtained with the preparation in the treatment of insomnia incident to pain or cough. Hypnal is free from the taste and caustic quality of chloral, and does not irritate the stomach. It is easily administered, especially to children.

Treatment of Diphtheria.

Dr. Waxham, of Chicago, writing on diphtheria, says that there is no specific for diphtheria, and insists upon clinging to old and well-established methods of treatment. The *frequent* use of iron in full doses, free stimulation, abundance of nourishment, watchful care, antiseptic gargles and washes for the throat and nose, strychnia and digitalis in case of depression, and the bichloride of mercury when the larynx becomes invaded—these remedies, he believes, are our sheet-anchors in the treatment of diphtheria, and no specific remedy can displace them; while isolation, ventilation and disinfection are safeguards that should *never* be omitted.

Oxyuris Vermicularis.— The oxyuris vermicularis is said to promptly disappear with injections per rectum of cod-liver oil, pure or made into an emulsion with the yolk of an egg. It is non-irritating, and is said never to have failed to effect a cure.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE PENNSYLVANIA STATE MEDICAL SOCIETY.

It has been unfortunate for the Medical Society of the State of Pennsylvania that two years should elapse between two successive meetings; but this became necessary on account of the unparalleled disaster associated with the name of Johnstown, which visited not only that town but at the same time a wide extent of the State, at the very date appointed for the meeting of the State Medical Society.

The long interval that has elapsed since the Society met in Philadelphia will probably make it harder to get a first-rate meeting this year than it would have been if only the usual interval had come between. It is probable that some men may have lost something of the zeal which they felt a year ago in regard to subjects they were then investigating, and that some of the discussions which were carried over from the Philadelphia meeting will suffer from this long interruption. Nevertheless, we trust that our professional brethren throughout the State will come up to the meeting determined to make it one of the best we have ever had.

It is now time for them to be notifying the Committee of Arrangements of the papers which they mean to read, and the topics they would like to have discussed; and we would urge them to be prompt in doing so.

There are several subjects which are pretty sure to come up for consideration, and the readers of the REPORTER might be preparing for them. Among these we think it safe to name the matter of the law for a State Board of Medical Examiners; the relation of superintendents of State Hospitals for the Insane to the management, and the nature and recent history of hydrophobia.

These and other topics of great practical importance ought to have full and free discussion; and it is to be hoped that some of them, at least, will be advanced to, or near to, definite conclusions. In regard to all of them very diverse opinions are held by different members of the Society, and these opinions ought to be thoroughly discussed, with an earnest determination to arrive at conclusions which shall be true to the demands of the profession and useful to our fellow-men.

In addition to such discussions of public questions, we hope there will be a good number of well considered papers on subjects of theoretical and practical medicine, and that the whole meeting may add to the reputation of the Society and of the physicians of Pennsylvania.

DIAGNOSIS OF FOLLICULAR TONSILLITIS.

At this season of the year, when both diphtheria and follicular tonsillitis are especially common, a physician is often called upon to make a diagnosis between

the two affections. Such a differential diagnosis is confessedly one of great difficulty. It is true that in some cases the physician is not compelled to express an opinion, and then he may keep his doubts to himself and await further developments before coming to a positive conclusion. In the majority of instances, however, he is asked, "What is the matter with the child, Doctor; is it diphtheria?" almost before his examination of the patient is completed. When the one who is thus cornered and compelled to state his opinion is the family oracle, whose patients hang upon his words, an expression of doubt as to the real nature of the case and a desire to delay before giving a decision, will be accepted as equivalent to saying that no one can make a diagnosis, so great is the obscurity. When, however, the practitioner is one less highly esteemed, a suggestion of doubt on his part as to the nature of the throat affection is likely to be met on the part of the family by doubt of the medical man's skill. But, whether he suffer in reputation or not, for his own peace of mind and from his love of scientific accuracy, he will desire to be sure of his diagnosis in every case. Practically, this may be unattainable; nevertheless, if sought for, a nearer approach to it will be made than though the practitioner were content to remain in doubt.

To begin with, it may be said, with a fair degree of accuracy, that follicular tonsillitis is more acute in its onset than diphtheria. In the latter affection, more than in the former, there is likely to be a history of preceding indisposition. The child appears to be ailing, with lassitude, perhaps peevishness, takes less interest in its playthings and has an impaired appetite. At the beginning, a chill, or various creepy, chilly sensations, are more common in follicular tonsillitis than in diphtheria. In the early stages, also, the throat symptoms are more marked in the former than in the latter. The child has some pain in deglutition; at times the degree of pain is far in excess of any manifest local disease. This is especially apt to be the case when influenza is prevalent; in such cases the throat is pale pink and œdematous. The tonsils at this time are seen to be somewhat enlarged, but they do not project beyond the arches of the palate. In a few hours one may be surprised to find that the temperature has risen to 102° or 103° Fahr., the tonsils swollen so as nearly to close the throat, and covered by a layer of thick, cheesy, yellowish-white exudation from the crypts of the tonsils. When they are seen in this condition the diagnosis from diphtheria can be made by remembering the well-known fact that the exudation described is on the tonsil, but not adherent to it; it can, therefore, be brushed off with a camel's-hair throat brush, or wiped off with cotton on an applicator. In diphtheria, on the contrary, the covering of the tonsil is a membrane, is adherent to it, so that in endeavoring to remove it the membrane comes off in pieces or strips and leaves a raw, bleeding surface beneath. Moreover, the color of the diphtheritic membrane is generally grayish, whereas, as stated, the exudation in follicular tonsillitis is generally of a yellowish-white tinge. In a few cases of a milder type, in which the constitutional symptoms also are less pronounced, instead of the characteristic deposit already spoken of there is a thinner, grayish-white layer, closely adherent to the tonsil. It is next to impossible to tell this kind of case from one of diphtheria by the throat symptoms alone. It will be in favor of tonsillitis if the disease developed rapidly following a chill, if the child has had rheumatism or growing pains, or if the other members of the family are inclined to be rheumatic or gouty.

The general aspect of the patient at times helps us to decide the question. The same amount of membrane on the tonsil will, if diphtheritic, produce more evidence of constitutional involvement than is the case in follicular tonsillitis, nothwithstanding the fact that the greater discomfort so far as the throat is concerned is experienced in the

latter affection, there is an indefinable something in the eye and complexion of patients which tells us that they are or are not seriously ill.

The result of treatment is also of value in diagnosis. The use of guaiac locally and internally frequently brings about a very rapid improvement in tonsillitis, but its use has no noticeable effect upon diphtheria.

Albuminuria is more common in diphtheria than in follicular tonsillitis, and this fact may be of service in deciding the question in a doubtful case.

The points of difference between these two affections are not many, and no one of them is sufficient in itself to enable us to make a diagnosis; the entire group of them, however, taken together and applied with calmness and clearness to the diagnosis of a doubtful case, will enable the practitioner to arrive at a satisfactory result in almost, if not quite, every case.

CAMPHORIC ACID.

The medicinal properties of camphoric acid have received but little attention at the hands of even the most recent writers on therapeutics. Biddle and Tidy merely mention it as a derivate of camphor by oxidation. Brunton, Edes, Farquharson and Wood, in their respective works on therapeutics, make no mention of it whatever. Merck's index speaks of its recent introduction into therapeutics, and mentions its use both by inhalation in diseases of the air-passages, and also as a surgical antiseptic.

The acid may be procured by prolonged boiling of nitric acid with camphor; the products of this oxidation being camphoric acid ($C_{10}H_{16}O_4$), and camphoranic acid ($C_9H_{12}O_5$). Attfield, however, gives the formula of camphoric acid as $C_8H_{14}(COOH)_2$.

Fürbringer was the first who called attention to the therapeutic properties of the acid. He classed it among the aromatic acids, and speaks of it as having antiseptic properties. Fürbringer used the acid in typhoid fever and enteritis, but although large doses were exhibited the drug failed to influence the process of the disease in any way.

In cystitis, especially in cases complicated by an ammoniacal decomposition of the urine, the acid checked the fermentation, but had no beneficial influence upon the suppurative process. An unlooked-for action of the drug was observed in tuberculous patients. Fifteen-grain doses exhibited three or four times a day, in most cases caused a complete cessation of the night-sweats. While Fürbringer was conducting his experiments in Vienna, Reichert, in Berlin, was similarly studying the action of this drug, with the view of ascertaining its value in acute and chronic diseases of the mucous membrane of the respiratory tract; also in certain cutaneous affections. Owing to the acid being but slightly soluble in water, a solution in alcohol and water was employed. In catarrh of the mucous membrane of the throat a one-half to two per cent. solution was used as a gargle with favorable results; the duration as well as the intensity of the disease being considerably lessened under its use. In cases of chronic catarrh a six per cent. solution was employed with highly satisfactory results.

Stimulated by these encouraging observations an investigation of the therapeutic qualities of camphoric acid was instituted by Niesel, at the Royal University Hospital of Greifswald, under the guidance of Professor Mosler.

Niesel employed the drug in solution with alcohol and water, as advocated by Reichert, and also in solution with water and glycerine; and finally in an alkaline solution: three parts of bicarbonate of soda to four parts of camphoric acid being used. As the alkaline solution was not stable, but became mouldy, after being kept for any length of time, it was always prepared immediately before its use. The results obtained with the drug were eminently satisfactory.

The most recent experiments with camphoric acid were also conducted in Professor Mosler's clinic in Griefswald, and the results are reported by Dr. Bernhard Hartlieb, in the *Wiener Medicinische Presse*, February 23, 1890. The drug was used in cases of acute and chronic catarrh of the mucous membranes of the respiratory tract; in acute and chronic cystitis; and in the night-sweats accompanying phthisis.

In angina and catarrhal pharyngitis a one-half to one per cent. solution was used as a gargle, and later a solution in glycerine of the same strength was similarly employed. The drug gave great satisfaction, and was very much liked by the patients. After an extensive use in this class of affections, it was apparent that the acid was equal, although perhaps not superior to other known remedies for similar disorders. In laryngitis the same results were obtained. The solution was also used for inhalation in eighteen cases of chronic bronchitis and pulmonary tuberculosis. While no apparent improvement in the objective symptoms of the disease was apparent, the subjective conditions of the patients were greatly improved under its use. The patients, without exception, declared that after the inhalations breathing became much easier, deeper inspiration was possible, and the oppressive feeling in the chest was greatly relieved.

Excellent results were obtained with camphoric acid in the treatment of cystitis. The cases treated were both acute and chronic. Recovery resulted in the chronic cases in from three to six weeks. The acid was used in a one-half per cent. solution; the bladder being washed out with this twice a day. The injections were prepared and given as follows: Ten parts of a twenty per cent. alcoholic solution of camphoric acid were added to four hundred parts of lukewarm water. Of this two syringefuls were injected into the bladder, and allowed to be immediately discharged; a third syringeful of the solution was then injected and retained for about fifteen minutes. When pyelitis existed in connection with cystitis, the drug was administered internally as well as locally. In cases of acute cystitis, where the injections produced considerable irritation, the acid was administered internally only; the dose employed was eight grains three times a day. The treatment proved very effective. It will be observed that the results obtained with camphoric acid in the treatment of cystitis, at the Greifswald clinic, were far more satisfactory than those reported by Fürbringer.

Finally, the acid was used in the treatment of the night-sweats incident to phthisis; and Fürbringer's conclusions regarding the drug's efficacy in this complaint were confirmed. The dose prescribed by Fürbringer was, however, found to be unnecessarily large. In most cases one fifteen-grain dose produced the desired result; in only a few stubborn cases thirty grains were required. The results obtained were eminently satisfactory. In a few cases the night-sweats did not entirely disappear, but were lessened to such an extent as to be no longer inconvenient to the patients.

It may be concluded that camphoric acid is relatively harmless. No gastric or intestinal irritation of any consequence was observed to follow its use. In one case of cystitis, fifteen-grain doses, administered three times a day, caused pain in the region of the kidney, which disappeared as soon as the use of the drug was discontinued. In two other cases of cystitis, when used as an injection, the drug caused a slight and but temporary swelling of the glans penis, which was speedily relieved by the application of lead-water. Still another patient vomited after taking a single dose of thirty grains of the acid; the same patient, however, was able later to take fifteen-grain doses without nausea. In the cases of phthisis in which the drug was employed, fifteen-grain doses were admirably borne; and in many instances this was increased to thirty grains without producing any but encouraging results.

From the foregoing it is evident that in camphoric acid we have a valuable therapeutic agent and one well deserving of a place in works on therapeutics. Camphoric acid is no new drug; yet its properties have been unrecognized until but recently. An important lesson may be drawn from this fact: a lesson which aspiring medical investigators would do well to follow, namely, that it is as important to conscientiously study the properties of already known drugs as to endeavor to invent new ones. The love for novelty is natural, and in the medical profession there is rather a tendency to be too much attracted by the pretensions of new drugs and to forget the value of old ones. In our pharmacopœia there are a large number of officinal drugs, the exact therapeutic properties of which are but slightly known, and which offer encouraging fields for study. We are heartily in sympathy with the profession in Germany, in their encouragement of the investigation of the properties of old and sometimes neglected articles of the materia medica, and we heartily commend the one we have just been discussing to the attention of the readers of the REPORTER.

UNIQUE CÆSAREAN SECTION.

A Cæsarean section of unusual interest was performed in this city, April 27, by Dr. Charles P. Noble, at the Kensington Hospital for women.

One of the most interesting features of the case is the fact that it was the second time that the same woman underwent the operation. She had been delivered two years ago by Dr. Howard A. Kelly, by Cæsarean section, and was the first woman to recover after this operation in Philadelphia, since the celebrated case of Mrs. Reybold, who was operated upon by Prof. Gibson, three generations ago.

As a result of the inflammatory conditions accompanying her first Cæsarean delivery, a utero-abdominal fistula resulted and has never closed permanently. Through this fistula the liquor ammonii discharged and labor came on about the eighth month of pregnancy. This woman is the third in this country who has twice been the subject of Cæsarean section. The case is, perhaps, unique in the existence of a utero-abdominal fistula, complicating pregnancy. The operation just performed consumed one hour, the patient being put to bed without shock, and with a pulse of eighty-four. A feeble, premature, male infant was delivered, which lived four hours.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

MODERN SCIENCE AND MODERN THOUGHT. With a supplemental chapter on Gladstone's "Dawn of Creation" and "Proem to Genesis," and on Drummond's "Natural Law in the Spiritual World." By S. LAING. Illustrated. 2 vols., paper cover, pp. 187. New York: The Humboldt Publishing Co. Price, 45 cents.

The success of this book in England has been such that a sixth edition was demanded within a month from the date of first publication. In it the principal results of Modern Science, and the revolutions they have effected in Modern Thought, are concisely presented, with a statement of the results of recent inquiries into the composition and constitution of the earth and of the universe into the nature and laws of matter, the development of organized and animated existences, the history of man, the myths of various races and the religions of various peoples, with discussions of the nature of force, motion, electricity, light and heat. Altogether it is a useful and instructive book and one well worth reading. Its cheap form is a special commendation.

LAPARO-HYSTEROPEXIE CONTRE LE PROLAPSUS UTERIN (NOUVEAU TRAITEMENT CHIRURGICAL DE LA CHUTE DE L' UTERUS). ANTERIOR ABDOMINAL FIXATION OF THE UTERUS. By PAUL DUMORET, Former Interne in Medicine and Surgery of the Paris Hospitals. Illustrated with eight wood-cuts. 8vo, pp. 168. Paris: Office of the *Progrès Médical*, 1889. Price, three francs, fifty centimes.

This thesis contains first a review of the operations hitherto performed for prolapse of the uterus, a criticism of their inadequacy to meet the requirements of the case, and then a description, illustrated with wood-cuts, of the comparatively new operation, fixation of the uterus to the anterior abdominal wall, as recommended by Terrier. The author objects to the term "ventro fixation," frequently used to define this operation, as an abominable combination. The operation of hysteropexy, he says, can be performed in

different ways: by fixing the uterine cornua to the abdominal wall (the procedure of Olshausen), by fixing to the wall the pedicle of an ovary (the procedure of John Phillips); or, finally, by fixing the anterior wall of the uterus to the edges of the incision into the abdomen (the procedure of F. Terrier).

Dumoret's own method of operating approximates closely to those of Lawson Tait, Hennig, Czerny, and especially Leopold, but differs from them in some details. In conclusion, the author says that surgical treatment of prolapse of the uterus is the only effective treatment, that hysteropexy is the preferable method and that while a serious, it is not a grave operation.

Dr. Howard A. Kelly's work in this line receives recognition and consideration, and he is, we believe, the only American writer mentioned. The thesis is an interesting contribution to the surgical treatment of prolapse of the uterus; it will be read with interest by those familiar with the subject.

Literary Notes.

—A life of Dr. Ephraim McDowell, the father of ovariotomy, is about to appear. It is written by his granddaughter, Mrs. Mary Young Ridenbaugh.

—The J. B. Lippincott Company announces that the third volume of the *Cyclopedia of Diseases of Children* will be ready this week. The delay in its appearance has been due to the large number of manuscripts and the elaborate nature of the volume.

Notes and Comments.

William F. Jenks Memorial Prize.

The second triennial prize, of four hundred and fifty dollars, under the deed of trust of Mrs. William F. Jenks, will be awarded to the author of the best essay on "The Symptomatology and Treatment of the Nervous Disorders following the Acute Infectious Diseases of Infancy and Childhood."

The conditions annexed by the founder of this prize are, that the "prize or award must always be for some subject connected with obstetrics, or the diseases of women, or the diseases of children;" and that "the trustees, under this deed for the time being, can, in their discretion, publish the successful essay, or any paper written upon any subject for which they may offer a reward, provided the income in their hands may, in their judgment, be sufficient for that purpose, and the essay or paper be considered by them worthy of publication. If published, the distribution of said essay shall be entirely under the control of said trustees. In case they do not publish the said essay or paper, it shall be the property of the College of Physicians of Philadelphia."

The prize is open for competition to the whole world, but the essay must be the production of a single person. The esssay, which must be written in the English language, or if in a foreign language, accompanied by an English translation, should be sent to the College of Physicians of Philadelphia, Pennsylvania, U. S. A., before January 1, 1892, addressed to Louis Starr, M. D., chairman of the William F. Jenks Prize Committee.

Each essay must be distinguished by a motto, and accompanied by a sealed envelope bearing the same motto and containing the name and address of the writer. No envelope will be opened except that which accompanies the successful essay.

The committee will return the unsuccessful essays if reclaimed by their respective writers, or their agents, within one year.

The committee reserves the right not to make an award if no essay submitted is considered worthy of the prize.

Treatment of Whooping-Cough.

Dr. J. F. Purdom, of Mitchellsburg, Ky., has an interesting article in the *American Practitioner and News*, April 12, 1889, in concluding which he says:

Owing to the fact that we are not able to abort pertussis, it occurs to me that the most rational line of treatment we can adopt is that which can be carried out in all cases with the greatest amount of convenience and safety of administration; provided we can obtain thereby favorable results equal to those derived from the use of more dangerous drugs, heroic treatment, or more troublesome forms of administration. And while I have no new remedy to offer in the treatment of the disease, I wish to give my experience with an old drug, the use of which has been and is yet based upon my idea of the pathology of whooping-cough.

The fact being established that pertussis is caused by a specific germ which confines itself to the nasal, throat and respiratory mucous membranes, has not changed in my opinion the fitness of the internal treatment which I have used during the past eight years. The drug which I employ is ergot. I find ergot mentioned by several writers, but the amount given and the frequency of the dose I have not seen stated, neither have

I seen mentioned the object to be attained by its use.

When I have diagnosed the case I prescribe fl. ext. ergot, given in wine or brandy, if objected to in water, every two or four hours, according to the severity of the symptoms; to a child of three months, five-drop doses, and to older children in proportion to age; and, as the urgent symptoms abate, I lessen the dose or extend the time, but continue the ergot until the spasmodic cough has ceased. My confidence in the curative effect of ergot is so settled that I tell the parents that so sure as they give the medicine as directed they will find improvement in the spasmodic cough inside of seventy-two hours. As a palliative in the early stage, I give in conjunction with the ergot a simple cough mixture composed of equal parts syr. ipecac, syr. squills, camphorated tinc. opium, and aromatic spts. ammon., with double the part of syr. tolu; dose according to age, and repeated as necessary to relieve the tenacity of the mucus and give rest at night. I regard it necessary as far as possible to have proper ventilation of the living apartments, with out-door exercise when the weather will permit. The feet should be kept dry and the body clothed with flannel during the course of the disease at all seasons, except the hot months of summer.

With a good, generous diet, I recommend all such hygienic measures as would tend to promote vigorous health. As will be at once seen, I do not claim any specific action for ergot, but believe it relieves congestion of the vessels about the medulla oblongata; also constringing the vessels of the parts invaded by the micro-organism, making the soil less fertile and the tenacious secretions less abundant, thereby making the enemy's stay of shorter duration, and at the same time cutting off his avenues for producing complications by lessening reflex irritability.

I have treated one hundred and three cases of whooping-cough with ergot and a simple cough mixture, and without a death. I have had neither capillary bronchitis, pneumonia, nor convulsions to arise after treatment was begun. Neither has there been any hemorrhage worthy of note. The spasmodic cough has lasted from seven days to four weeks; and there has been seldom a tonic course of treatment required in the stage of decline, as a result of anemia or retarded convalesence.

Distemper in Dogs.

Although dogs enjoy the friendship of man far beyond any other animal, except perhaps the horse (and with elderly ladies the cat), their diseases have attracted very little attention, and when they fall ill they are left to the tender mercies of the nearest "vet." whose skill is by no means always on a par with his reputation. The subject of rabies, it is true, has been carefully inquired into, but the explanation of this departure from our usual indifference is to be found in the fact that human beings are liable to contract the disease, and the exception testifies to our egotism rather than to our humanity. One would have thought that a disease like distemper, which annually claims as its victims thousands of the young and beautiful of the canine race, would long ere this have been investigated and means devised for protecting our quadrupedal friends from the fate in store for them. We are pleased to record that at last this subject has found its Pasteur, and that the possibility of averting distemper now seems to be within measurable distance. Mr. Everitt Millais has carried out a series of bacteriological observations and experiments at the laboratory of St. Thomas's Hospital, the results of which, so far as they go, point to the practicability of affording an immunity against the disease by inoculation with a modified virus. Their number does not authorize any absolute conclusions, but the record is decidedly encouraging, and should pave the way to observations on a larger scale. Mr. Millais has proved, at any rate, that the malady is due to the presence of one or more micro-organisms, and the rest of his experiments were carried out on the lines which have yielded such brilliant results in respect of other diseases. — *Med. Press and Circular*, April 16, 1890.

Death from Pressure on the Fontanelle.

An old woman in Tranquility, near Easton, Pa., recently showed several children the fontanelle, or "soft-spot" on the head of a baby four months old. After the woman left the house the curiosity of the children became aroused, and all of them pressed down on the soft spot when they had a chance.

The story of one of the children was that every time she put her finger on the soft spot

the baby cried; that she did not know she was doing wrong. The infant was taken sick, inflammation of the brain set in, and death followed. The father had one of the self-accused children arrested, but the Prosecuting Attorney directed the complaint to be dismissed on the ground that if a crime had been committed the accused was not responsible for it.

Terpin Hydrate in Whooping-Cough.

In the *Wiener med. Presse*, March 23, 1890, it is reported that Dr. Wilhelm Manasse has had good results from the administration of terpin hydrate in cases of whooping-cough. He gave to children under one year old as much as twenty-two grains without any disturbance of the urinary or digestive apparatus. With doses of forty-five grains in twenty-four hours, no albumin or blood was found in the urine. Manasse used terpin hydrate in forty-one cases, the patients ranging in age from nine months to twelve years. In general he found an improvement in the patients, with diminution of frequency and severity in the spell of coughing, in four or five days after beginning to use the remedy, when the quantity varied from about twenty to about forty-five grains per day according to the age of the child.

Manasse calls special attention to the bronchial catarrh of whooping-cough and the influence of terpin hydrate upon it. He gave the drug in powder about seven and a-half grains to 15 grains three times a day.

NEWS.

—The Health Office of Jackson County, Mississippi, has reported a case of leprosy in that county. Steps have been taken by the State Board of Health of Mississippi to isolate the case.

—Professor W. W. Keen, M. D., has resigned the position of lecturer on art anatomy at the Academy of the Fine Arts of Philadelphia, and Dr. George McClellan has been chosen as his successor.

—Dr. G. Frank Lydston, of Chicago, has been invited to deliver the opening public address before the Kentucky State Medical Society May 14. His subject will be "Materialism *vs.* Sentiment in the Study of Crime."

—The sixth annual meeting of the National Conference of State Boards of Health will be held at the Maxwell House, Nashville, on Monday, May 19, preceding the annual meeting of the American Medical Association.

—Dr. Samuel B. Swavely, whose expulsion from the Pottstown, Pa., Medical Society was recorded in the REPORTER, Sept. 28, 1889, was arrested in Pottstown, April 29, for criminal malpractice and held in $700 bail.

—The annual dinner of the Medical Alumni of the University of Pennsylvania took place April 30. Speeches in response to toasts were made by Provost Pepper, Mr. Talcott Williams, and Drs. Mitchell, Keen, Billings and Wood.

—Dr. E. W. Pritchard, of Coldwater, Kansas, and an attorney, met at a muddy crossing on May 2, and became engaged in a quarrel as to whom should be given the most room to pass. Dr. Pritchard was finally thrown into the mud. Directly the men came to blows, which ended with the attorney hitting his opponent with a revolver, felling him to the ground. Dr. Pritchard died on Saturday afternoon.

—Dr. Ryland Brown died in Indianapolis May 2, at the age of eighty-three years. In 1858 he accepted the Chair of Natural Science in the Northwestern Christian University, in Indianapolis. During the last two years of that period he filled the Chair of Chemistry in the Indiana Medical College. In 1872 he was Chemist-in-Chief of the Agricultural Department at Washington. He was the author of a work on physiology, which was used as a text-book for many years in the schools of Indiana.

—At the last examination of the candidates for the position of residents at the Philadelphia Hospital the following physicians were appointed, after a competitive examination: Drs. William S. Carter, John H. Rhein, Frances S. Janney, Frances C. Van Gasken, Edwin P. Teuter, Samuel T. Buck, Nathaniel J. Dundelberger, Samuel P. Eagleton, Carl A. Hamann, Gregory H. Hoonanian, Frederick P. Reynolds, Henry N. Doan, Howard S. Anders, Daniel E. Morris, Charles S. Martin, James L. Leys, Thomas G. McConkey, Mrs. Esther L. B. Mathews, Joseph L. Nicholson and George M. Muttact. Thirteen of the successful candidates were graduates of the University of Pennsylvania; three of the Woman's Medical College; three of the Medico-Chirurgical College of Philadelphia, and one of the Jefferson Medical College.

EDITOR AND PUBLISHER,
N. E. COR. 13th & WALNUT STS., PHILADELPHIA.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

SPECIAL and RELIABLE FORMULÆ for PHYSICIANS' PRESCRIBING

The Coating will Dissolve in 4½ Minutes.

PIL. SUMBUL COMP.
(Wm. R. Warner & Co.)

(DR. GOODELL.)

℞—Ext. Sumbul.....1 gr. | Ferri Sulph. Ext.....1 gr.
Assafœtida.....2 gr. | Ac. Arsenious.....1-30 gr.

"I use this pill for nervous and hysterical women who need building up." This pill is used with advantage in neurasthenic conditions in connection with Warner & Co.'s Bromo-Soda, one or two pills taken three times a day.

PIL. LADY WEBSTER.
(Wm. R. Warner & Co.)

℞ Pulv. Aloes.....2 gr. | Pulv. Rose los.....½ gr.
" Mastic ..... ½ gr. | M. ft. one pill.

Lady Webster Dinner Pills. This is an excellent combination officially designated as Aloes and Mastich, U. S. P. We take very great pleasure in asking physicians to prescribe them more liberally, as they are very excellent as an aperient for persons of full habit or gouty tendency when given in doses of one pill after dinner.

PIL. ALOIN, BELLADONNA, AND STRYCHNINE.
(Wm. R. Warner & Co.)

℞—Aloin, 1-5 gr. Strychnine, 1-60 gr. Ext Belladonna, ⅛ gr.

Medical Properties—Tonic, Laxative. Dose, 1 to 2 Pills.

Try this Pill in habitual constipation.

PIL. ARTHROSIA.
(Wm. R. Warner & Co.)

FOR CURE OF RHEUMATISM AND RHEUMATIC GOUT.

Formula.—Acidum Salicylicum; Resina Podophyllum; Quinia; Ext. Colchicum; Ext. Phytolacca; Capsicum.

Almost a specific in Rheumatic and Gouty Affections.

PIL. CHALYBEATE COMP.
(Wm. R. Warner & Co.)

Same as Pil. Chalybeate, with 1-6 gr. Ext. Nux Vomica added to each Pill to increase the tonic effect. Dose, 1 to 3 Pills.

PIL. DIGESTIVA.
(Wm. R. Warner & Co.)

A VALUABLE AID TO DIGESTION.

℞—Pepsin Conc't.....1 gr. | Gingerine.....1-16 gr.
— Pv. Nux Vom..... ¼ gr. | Sulphur.....⅛ gr.
IN EACH PILL.

This combination is very useful in relieving various forms of Dyspepsia and Indigestion, and will afford permanent benefit in cases of enfeebled digestion, where the gastric juices are not properly secreted.

As a dinner pill, Pil. Digestiva is unequalled, and may be taken in doses of a single pill either before or after eating.

GLYCOZONE

Is used as an internal remedy, or for local dressings. It is absolutely harmless; and Ozone is its healing agent.

GLYCOZONE, by its wonderful antiseptic and healing properties, not only prevents the fermentation of the food in the stomach, but it quickly cures the inflammation or irritation of the mucous membrane. It is a specific for disorders of the stomach. **Dyspepsia, Catarrh of the Stomach, or Gastritis, Ulcer of the Stomach, Heart-Burn.** Sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing CHAS. MARCHAND'S label and signature.

Prepared only by Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

A book containing full explanations concerning the therapeutical applications of GLYCOZONE, with opinions of the profession, will be mailed to physicians free of charge on application.

GLYCOZONE	¼ lb. bottle, retail price,	$1.00
	½ lb. " "	1.75

AGE OF FETUS — CHANGES IN COLOR OF NEW-BORN.—CARE OF THE BREASTS IN PREGNANCY.—PUERPERAL SEPTICEMIA.[1]

BY THEOPHILIS PARVIN, M. D.,

PROFESSOR OF OBSTETRICS AND OF THE DISEASES OF WOMEN AND CHILDREN IN THE JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

Age of Fetus.

Gentlemen: A woman was delivered recently at the Maternity of a dead fetus, which is now presented to you. You observe that it is macerated, and therefore had been dead some days. An interesting question relating to the fetus expelled dead or living is: Can we determine, at least approximately, how far development had advanced, or, in other words, what was the age of the fetus? The following table from Auvard I believe will be useful to you in deciding this question:

About the middle of the fourth month the fetus is 20 centimeters long.

About the middle of the fifth month the fetus is 25 centimeters long.

About the middle of the sixth month the fetus is 30 centimeters long.

About the middle of the seventh month the fetus is 35 centimeters long.

About the middle of the eighth month the fetus is 40 centimeters long.

About the middle of the ninth month the fetus is 45 centimeters long.

And at the end of nine months, 50 centimeters long.

Changes in Color of the New-Born.

The two infants, each about a week old, presented for examination, some of you correctly state are affected with jaundice, a condition so common and so free from

[1] Delivered at the Philadelphia Hospital.

danger, that it is known as physiological jaundice. The discoloration of the skin usually comes two or three days after birth, and in eight or ten days fades away, without having, in the meantime, caused the child any discomfort. Various explanations have been given of this condition: One of these is that it results from slight hepatitis, while Frerichs attributes it to the lessened supply of blood passing to the liver, immediately after the cord is tied, and hence a relative anemia of the hepatic capillaries; and this deficiency is compensated by the passage of bile from liver cells into the capillaries. Another hypothesis is that blood exuding into the skin is freed of its coloring matter, and this hypothesis is strengthened by the fact that the coloring matter of bile is not found in the urine of these infants. New-born babes usually pass through certain changes of color. The skin after the detachment of the vernix caseosa is quite red, and becomes deeper in hue as desquamation goes on. Then in two-thirds or three-fourths of all cases the physiological jaundice referred to appears. After the completion of desquamation and the passing away of the jaundice the skin has its pinkish white or flesh color.

Care of the Breasts in Pregnancy.

You know that the mammiferæ compose one of the great classes of the animal world, including some three thousand species, and foremost in this class is man. The word mamma—Greek, Latin and English—which the child first utters—was primarily applied to the breast. More than one of the old Roman writers refers to the infant calling *matrem mammam* as it did *patrem tatam*, a term which is said to survive in the word dad or daddy applied sometimes nowadays to the father. Mamma and dada are the first, or among the first, words uttered by the child. There seems to be a fitness in the secondary use of the word "mamma" as expressing an affection, probably purely animal in its origin, for her who supplies the infant with the nourishment, from her breasts, which it needs—the name of the source of food given to the person who has that source.

You know that woman is uniparous, and it is only exceptionally that she gives birth to more than one child at a time. And, according to the general law prevailing among all animals usually producing but one offspring at a birth, woman has one pair of breasts. Fortunately for woman's comfort and convenience these organs are placed upon the anterior portion of the thorax, and not, as in some other of the mammiferæ upon the abdomen, in the flanks, or upon the back. Her breasts are rarely symmetrical, the right being usually somewhat larger than the left, the opposite being the case probably in left-handed women. You know that each breast is composed of lobes, these of lobules, and the lobules of acini; that excretory ducts corresponding in number with that of the lobes, carry the milk to the summit of the nipple, there opening, and that before passing up in straight tubes in the nipple, they present large expansions called milk-sinuses. When these sinuses are enlarged, distended with milk, they are popularly known as "milk cords." Each canal is surrounded by connective tissue, rich in elastic fibres, which become increased five or six times during lactation. But beside this, these canals have, external to the connective tissue, abundant muscular fasciculi, some longitudinal, others horizontal, and others oblique. The horizontal fibres are the most numerous, and by their contraction cause the nipple to project, and in some cases the compression of the sinuses is so strong that just when the mother is about to give the nipple to the infant milk may be forced in a stream some inches in length. As the horizontal muscular fibres by their action cause a projection, so the longitudinal fibres similarly acting, cause a retraction of the nipple; and probably most of the cases of retracted nipple are to be attributed not to abnormal shortness of the milk-ducts so much as to the predominance of the action of the longitudinal muscular fasciculi, a view which has some confirmation in the fact that often by perseveringly "drawing out" the nipple it can be given good shape, the resistance of these fibres being thus overcome.

In the three women whose breasts you now have an opportunity of examining, you will observe that these organs are apparently well-formed, even presenting somewhat larger size than usual. But the mere size of the breast is no proof that a woman will furnish an ample supply of milk; for the glandular structure may be deficient, the great mass of the breast being formed of fat. Generally a somewhat conical breast, and not a very large one promises better, so far as lactation is concerned. There is a surer promise of milk than the size or form of the

breasts. If there is an abundant secretion during pregnancy, it will be abundant when the time for nursing comes. Possibly some of you knew what it was, when boys, to drive the cows from clover-field to the milking-yard. I certainly did, and the air was no richer "when the early dews were falling" in the summer evening with the aroma of the sweet-scented clover, than with that of the milk dripping, dropping from the swollen udders. You knew that the buckets would be readily filled from these cows, who had been on such lactigenous diet. When a pregnant woman complains that she is always wet from oozing milk, her clothing stained with it night and day, comfort her for the inconvenience she now has, by assuring her that she will have an abundant supply of nourishment for her babe. Another sign of some value, though not so readily available, is the presence of lactose in the urine; a pregnant woman who has lactosuria will surely prove an excellent nurse.

The woman whose breasts I ask you now to look at has nipples scarcely elevated above the surface—indeed if it were not for the difference in color between the general surface of the breast and that part occupied by the areola and nipple, one could hardly recognize that the latter existed at all. What these nipples need is education, taking the word in its literal sense; they should be educed, drawn out. But how?

The simplest method is to have the woman use her thumb and finger, seizing the organ between them, and draw it out; let her do this ten minutes each day three or four times; further, she must be careful that there is no pressure from her clothing upon the nipple, and that space is given it for development—indeed, the use of a solid nipple shield will assist in its proper formation. A breast pump gently used may be employed, or simply a four-ounce bottle, the mouth of which will readily enclose the nipple, and into this bottle hot water is put for two or three minutes, poured out and immediately the mouth of it put over the nipple—the condensation of the vapor in the bottle causes a vacuum, and atmospheric pressure forces the nipple in. I am not at all apprehensive of the least danger of interrupting the pregnancy—though some have expressed such fear—by any of these means properly used.

One word more as to the care of the nipples during pregnancy, for it is not enough to give them proper form, or, having such form already, to ensure uninterrupted lactation; they must be put in such condition that they will not probably suffer injury from nursing and will not become excoriated or fissured. It is many years since I first entered my protest against the means then, and still, commonly employed to prevent these accidents, that sometimes have such grave consequences in mammary abscesses and arrest of lactation. The means generally used are astringents and alcohol. My saying anything upon the subject seems very much like what poor Hood termed the piscatorial precept, "line upon line," for I have so often expressed my views upon the subject. Nevertheless as the constant dripping of water wears away the stone, so the frequent repetition of that view and the practice which is its sequence, may, if true, become generally accepted, and thus be beneficial.

First, though in regard to this point there is no dispute, the nipples ought to be kept scrupulously clean, by employing the means most used for securing cleanliness: soap and water; otherwise the secretion which oozes from them dries upon the surface, and when detached exposes a sensitive surface. But the nipple when in use is subjected to the action of warm moisture, and such action has a tendency to soften the epidermis and thus cause its detachment. Further, the nipple in use ought to have its surface pliable and yielding, not stiff and resisting. We know what nature does for inferior orders of animal life who are especially exposed to the action of water, for example. The ducks, for illustration, have no whiskey and alum or tannin reservoirs to cover their surface with as a protection in rain or pond or stream; but nature has given them an abundant supply of oil for this purpose. Nature has supplied the nipple with a vast number of sebaceous glands, just as she has the nymphæ, and for similar purpose. These glands of the nipple are increased in size and activity during pregnancy and lactation. And now comes an art most meddlesome and mischievous, I think, seeking with preparations of alcohol to dissolve and remove this fatty secretion, and by astringents to lessen the activity of the glands. Further, so far as the skin is concerned, the effect of these preparations is to render it harsh, dry, and resisting instead of soft and pliable. My belief is that letting the nipples alone would be far better than this practice. Nevertheless better than doing nothing, is

applying once a day to the nipple a little cocoa butter, such application compensating for the fatty matter that has been removed by soap and water. If the patient desires anything more she may bathe the nipples once a day with a little tincture of arnica or cologne and water. Daily exposure of the nipples to the air for a short time has been also recommended as a prophylactic against the traumatisms of lactation.

Puerperal Septicemia.

The patient now presented, was brought to the Hospital suffering with septicemia, some week or ten days ago; she had been delivered a few days before her admission. There were diphtheroid—I will not say diphtheritic—ulcerations in the vagina and vulva. The curette was used in the uterine cavity, and the latter was washed out with a 2 per cent. solution of creolin; the ulcerated surfaces were cleansed and then swabbed with a mixture of carbolic acid and iodine. The patient's temperature upon admission was 103°, her respirations 36 and her pulse 118 to the minute. She is now completely convalescent, and I believe the local treatment has been her salvation.

This case illustrates a fact which cannot be too strongly emphasized. The cases of puerperal septicemia now seen at this Hospital are almost invariably those in which the disease originated outside; for so careful are resident doctors and nurses in the employment of aseptic precautions and of antiseptic means, that for a woman whose delivery takes place in the Maternity to have even mild septic infection is very rare. Only a few years ago, in entering upon my term of service, I would find two, three or more cases of puerperal septicemia transmitted to me by my predecessors, and several new cases would originate during my attendance. Some of these patients died although, of course, the large majority recovered. Experience has proved here, as in other lying-in hospitals, that this disease is preventable: and those who have given most study to the causes of puerperal infection hold that the origin is to be sought not in place or season, but in person; not in locality or in time of year, but in the individual who has charge of the woman in labor and in the puerperal state. As I have previously said, in this room, to an audience of nurses, the question naturally arises in every case of puerperal infection, "Who has sinned, the doctor or the nurse, that this woman perishes or is in peril?" It is only exceptionally that one or the other of the parties referred to does not deserve blame. The presumption is that there has been an error of commission or of omission on their part, and the day surely comes when neither the public nor the profession will hold them guiltless. One of the most astonishing incredulities of certain members of the profession is the utter disregard for antiseptics in obstetric practice; you will read in medical journals occasional contributions condemning these means, at least indirectly; statistics of this and of that physician who ignores antiseptic agents, showing either a slight puerperal mortality, or none at all, from septic disease. The first thing to be observed is that this is merely negative evidence, and of comparatively little value. Next, that although these gentlemen have no septic mortality recorded, are they quite sure that there have been no cases of septic morbidity in their practice, a morbidity which may have permanently injured patients thus affected. Puerperal infection presents various characters, and the diagnosis is, in some instances, very difficult. Further, though two or three, or a dozen physicians, practicing in the country, present such favorable obstetric statistics, it is possible that an equal number of others, also ignoring antiseptics, could be found who have had no such favorable results. I believe that there is a larger proportional number of cases of puerperal infection in the country than in the cities, for the last census shows that the puerperal mortality is ten per cent. greater in the former than in the latter. Considering the greater vigor of the woman living in the country; the purer air and the simpler food she has, and considering, further, the vast number of child-bearing women in cities who, from poverty and ignorance, are in wretched hygienic circumstances, one might reasonably expect the mortality percentage to be the very opposite of what it is.

The fact that has been stated is worthy being pondered by every country practitioner, and especially by those who from their own limited experience and from that of a few others, are trying to impress the profession with the notion that antiseptics are unnecessary in obstetric practice.

One fact, which leads me to attach less importance to the opinion of a few of these gentlemen, is that they are believers in the autogenesis of puerperal septicemia in cer-

tain cases, a convenient defence for a reproaching conscience if the disease occurs in their practice. My own belief is that there is no such thing as so-called autogenetic puerperal fever, that in almost all instances the external origin of the disease can be established beyond reasonable doubt, so that the exceptions prove the rule. Autogenesis, like the kindred doctrine of spontaneous generation, perishes in the light of scientific truth.

In a future lecture I hope to consider the prophylaxis of puerperal infection, and the diagnosis and treatment of the diseases resulting from such infection.

FRACTURE OF THE ULNA; NECROSIS.—SARCOMA OF THE RECTUM; COLOTOMY.—RESECTION OF THE WRIST-JOINT.—OSTEITIS OF TIBIA; TREPHINING.[1]

BY JOHN H. PACKARD, M. D.,

ATTENDING SURGEON TO THE PENNSYLVANIA HOSPITAL, ETC.

Necrosis of Bone.

Gentlemen: The first case that I shall show you this morning is one which you saw about two weeks ago. I told you that the patient, a boy eight years old, had sustained a fracture of both bones of the forearm near the wrist-joint, and that this had been followed by some necrosis, a sinus leading down to the dead bone. But I could not then determine exactly the extent of the damage, and there was a considerable degree of inflammation of the soft parts. It was, however, certain that union of the fracture could not be hoped for until the dead portion of the bone was removed. I resorted to an old-fashioned but valuable remedy—a poultice—for the reduction of the inflammation; and then had the child etherized, enlarged the sinus, and readily extracted the piece of bone which I here show you. It is the lower end of the diaphysis of the ulna. You know that the long bones are developed by growth from centres of ossification, one being in the middle of the diaphysis or shaft, and the others in the epiphyses at its extremities. Here the fracture took place near the end of the diaphysis, and the small lower fragment, being insufficiently nourished, died; after which it acted as a foreign body, and relief could only be had by its extraction or extrusion. My hope is that the end of the upper or main fragment may unite with the epiphysis; and in order to favor such an occurrence I have dressed the limb with the hand drawn towards the ulnar side, thus reducing to a minimum the gap between the two portions.

Result of Colotomy.

I shall now show you the result of an operation which I performed about two years ago for the relief of a very distressing affection—a sarcoma of the rectum. The patient, who gave her age as about 60, suffered greatly from constipation, the walls of the bowel being thickened and stiffened by the cancerous deposit in their substance. When the fecal matter was thin, it came away, but irritated the surface over which it passed; and its evacuation was always followed by a severe and long continued sense of spasmodic contraction, although the muscular coat probably could not really act in lessening the calibre of the gut. In order to give relief it was necessary to make an artificial opening into the canal, well above the seat of the disease. Remember the course of the colon or large intestine; as it descends along the left side of the belly, it runs (almost invariably) behind the peritoneum, and may be exposed and opened in the lumbar region, without injury to the serous membrane. Beginning at the upper and outer corner of the quadratus lumborum muscle, I divided the tissues outward and downward almost as far as the crest of the iliac bone. Layer by layer was cut through, until I came to the bowel, which I opened, and stitched the edges of the orifice to those of the wound in the skin. Healing took place very readily, and the fecal evacuations have been through this artificial opening ever since. The patient has gained flesh and strength, and has been about her usual avocations. Of course the disease has not been cured, but the suffering caused by the contact of fecal matter with the probably ulcerated surface has been wholly relieved. There are no involuntary evacuations, and nothing would indicate to those about the woman that she has an artificial anus. Some high surgical authorities have condemned this operation, on the ground that it placed

[1] Delivered at the Pennsylvania Hospital, Dec. 18, 1889.

the patients, they thought, in a condition so disgusting to themselves and those around them that death would be preferable. Such a result I have never seen. In the first case in which I operated, in 1873, the patient was made extremely comfortable, and lived so for eight months, when she succumbed to the original disease, the womb being involved as well as the bowel.

Resection of Wrist-Joint.

This patient was before you two weeks ago, and you will remember that I then told you that she had sprained her wrist about four weeks previously. Why, I cannot tell, but in this case this slight injury has been followed by destructive inflammation in the joint. Her pain has been intolerable, and I have advised amputation through the forearm; but she naturally shrinks from this, and I shall therefore resort to resection of the diseased bones. This is an operation which is not often done, and which rarely gives a satisfactory result; but I am willing to make the attempt to save this poor woman's hand, even if its complete usefulness cannot be restored.

Let me say that I should not advise any interference, but for the fact that even with thorough extension it has proved impossible to relieve the pain of which this patient complains by day and night. Extension has been made here by means of rubber adhesive plaster, one strip around the hand and the other around the upper part of the forearm, the ends being then brought around the ends of a straight splint reaching from the elbow to the tips of the fingers, and joined by a loop of bandage; the degree of tension is of course determined by the pull exerted on this as it is tied.

Various plans have been adopted for excising the wrist; the one which I shall employ will enable me to avoid injury to the tendons, and thus to preserve as far as possible the usefulness of the hand. I shall make at the outer side of the joint a slightly-curved incision, about three inches long, and at the inner side another. Cutting right down to the bone, I find it roughened, and the periosteum loosened from it. By means of this strong steel elevator I detach the periosteum at the front and back of the ulna, and then do the same for the radius; I now push this eyed probe across both bones, beneath the periosteum, and of course beneath all the tendons, and threading the eye with a ligature I am enabled to draw a chain-saw through. Protecting the soft parts by this bone-director on the dorsal side of the bones, I divide these latter, and extract them with bone-forceps. Finding now that the upper row of carpal bones are diseased, I dissect them out, using for the purpose a blunt bone-knife. You will note that although no named vessels have been injured there is very free bleeding; this is always to be looked for when we are dealing with inflamed bone or periosteum. A free irrigation with hot sublimate solution will materially control it, and it will be quite checked by dusting in powdered iodoform.

Passing a rubber drainage-tube through from one side to the other, I close each wound with three or four points of catgut suture, apply the usual dressings, and place the part in a Levis's splint.

Understand distinctly that I have very little expectation of the restoration of usefulness to this hand; but I know that what has been done will take off tension, and possibly the result may prove better than we can venture to predict.

[The wounds in this case healed very well, and in a few days the patient ceased to complain of pain in the part; she suffered severely from an attack of "grippe," but was discharged, very well satisfied, in February. The ultimate result cannot yet be pronounced upon.]

Osteitis of Tibia.

This patient, a girl aged nineteen, has inflammatory softening of the upper part of the tibia—a very frequent seat of such trouble, which sometimes terminates in the formation of abscess, and is very painful from the unyielding character of the structure. About three months ago I operated on this patient, trephining the wall of the bone; but the relief given was only temporary. I lay the bone bare by an incision through the cicatrix of the one formerly made, turn the periosteum aside, and apply the trephine close to the same spot as before. The bone is evidently softened. I carry the instrument on through the cancellous structure, until it ceases to meet with resistance. Now I pass a probe through the trephine-hole, and it enters a cavity, which may be the upper end of the medullary space. There is rather free bleeding, but it is checked by irrigation with hot sublimate solution. I put in a drainage-tube, and apply the usual antiseptic dressing. It would not have surprised me had the trephine opened an ab-

scess-cavity, nor indeed if a central necrosis had been exposed; but I believe this operation will be effectual in relieving the patient.

[This patient had no further pain, and the wound healed very readily; she was discharged, cured, early in the month of January.]

COMMUNICATIONS.

SUCCESSFUL SUPRA-PUBIC LITHOTOMY IN AN OLD MAN.

BY J. McFADDEN GASTON, M. D.,
ATLANTA, GA.

Being summoned to West Point, Ga., by J. S. Horsley, M. D., to co-operate with him in the management of an old gentleman's case, I learned that he had been treated previously by another member of the profession, with bougies for the dilatation of his urethra. He had failed to discover the true cause of his troubles upon sounding the bladder, and declared, upon hearing that stone had been detected by Dr. Horsley, that he would eat all the calculi that might be taken from the patient's bladder.

Upon a full investigation of the case I concurred in the propriety of an operation, not simply for the removal of the calculi, but for subsequent drainage of the bladder to relieve the cystitis.

While there were some considerations favoring perineal incision, greater advantages were presented for the supra-pubic operation.

Before giving the details, I will note the previous record, made by Dr. Horsley: "Lee, James, white, 76 years old; saw case first on October 27, 1889. Patient gave history of having suffered from bladder trouble for three years; had been under care of various physicians, some of whom had examined for calculus, but without success."

Examination of urine showed it loaded with crystals of triple-phosphate and uric acid. One week later an exploration with Thomson's sound revealed the presence of a stone, apparently about one-half inch in diameter. On November 20, 1889, after some preparatory treatment, an attempt was made, with the assistance of Drs. Patillo and Winston, to crush the stone with Civiale's instrument. The stone could not be grasped, although the patient was etherized. On November 28, however, the patient being etherized by Dr. Patillo, and Dr. Winston acting as assistant, litholopaxy was successfully performed, and two stones, one-half and one-seventh inches in diameter, were crushed and were evacuated with Otis' apparatus. No more calculi could be felt at the time.

The patient bore all the manipulations well, but continued to suffer with the evidences of calculus. Examination revealed —though imperfectly—the presence of calculi; but attempts with Civiale's and Bigelow's instruments failed to catch the stone. The patient's sufferings increasing, supra-pubic cystotomy was decided upon.

This operation was undertaken March 17, 1890. A hypodermic of one-fourth grain of morphia and one-one-hundred-and-fiftieth of a grain of atropia was administered by Dr. Winston, and the anæsthetic of A. C. E. mixture was entrusted to Dr. Patillo, with the assistance of Mr. J. Patillo.

As soon as the patient was unconscious the searcher was introduced by Dr. Horsley, who verified his former diagnosis of the existence of several calculi, which was then confirmed by the examination of Dr. Gaston.

An elastic catheter was then introduced into the bladder and its cavity was washed out with a warm solution of boric acid until it returned clear. At this stage a Barnes's uterine dilator was rolled lengthwise and passed into the rectum. A warm solution of boric acid was injected into the bladder until it contained seven ounces. Eight ounces of warm water being injected into the rubber bag in the rectum, the prominence of the bladder above the pubic bone was detected by the hand over that region. The pelvis was raised by placing a pillow under the hips of the patient.

Dr. Horsley now proceeded to make an incision three inches in length in the median line, extending from the pubic bone upward and dissected through the adipose tissue and fiscus until the cut was carried in the central part down to the cellular tissue covering the bladder.

It was thought best, with a view to lift the peritoneum higher, that the injection should be increased; and as Dr. Horsley had verified on a previous occasion from retention of urine, a capacity of ten ounces for the bladder, the injection of fluid into it was increased to that extent; and the injection in the rectal bag was carried to

twelve ounces. There was no longer a doubt in regard to the removal of the peritoneum from the field of operation by a finger hooked into the upper angle of the wound, and with a teneculum securing the walls of the bladder at the lower angle, a cord of four threads of silk was carried through the wall of the bladder on each side. These being looped by knotting the ends were held by assistants while the final cut into the bladder was made between them to an extent for the finger to be introduced, when the presence of numerous calculi was detected. With the aid of stone-forceps a calculus corresponding to the size of a partridge egg was immediately extracted, and others of smaller size were removed with the same instrument, when the further progress was interrupted by passing two stitches of iron dyed silk on each side through the margins of the bladder and skin so as to approximate the cut edges. The boric solution was now thrown fully as a douche into the bladder, and the search for calculi with the finger was resumed by Dr. Horsley, and he succeeded in extracting in all twenty-eight calculi of various shapes and sizes. The warm boric solution was passed again into bladder and allowed to run out of the incision,until it was free from stain of blood or admixture of any kind.

A very remarkable projection into the bladder was caused by the enlarged prostate gland, and it was found that while there was no difficulty in passing a No. 32 bougie through the urethra, it could not be made to emerge into the cavity of the bladder, owing to the obstacle of the prominent prostate. It was not thought expedient to add to the risks of the patient by attempting any operation upon the prostate on this occasion ; and yet at a future day an excision of the middle lobe may be practicable.

The bladder wall was considerably thickened and its structure rather brittle, as was found by the teneculum tearing out when a strain came upon it from the escape of fluid by incision, and its feasibility was also shown by the needle turning out when first inserted through a small portion of tissue. This would indicate that caution should be observed in not carrying the distention too far by injecting, lest rupture into the cavity of the abdomen might occur.

Two drainage-tubes, consisting of soft catheters, were secured in the lower angle of the incision by attaching them to the cords left in the walls of the bladder and condoms were attached to the outer ends to receive the urine. The upper angle of the wound was packed with iodoform gauze, and absorbent cotton was placed over all and a rubber passed around the pelvis.

The patient rallied promptly from the A. C. E. anæsthetic and had no nausea or vomiting subsequently. He complained of general discomfort in an hour after consciousness returned, and another hypodermic of morphia and atropia was given, with a happy effect.

Prior to the operation the temperature had been normal and the pulse about 100 to the minute ; and upon examination during the afternoon there was no change of consequence.

On the next day Dr. Horsley's report at 7 A. M. was: pulse 100, temperature 100°, respiration 20 ; at 2 P. M., it was: pulse 84, temperature 100°, respiration 20 and the patient resting well.

March 20, he reported continued progress; pulse 80, temperature 98.7°, appetite fair, bowels moved by means of Rochelle salts. The patient rested fairly well last night and is bright and cheerful; the wound looks well, drainage does well, kidneys are acting well and the case is altogether hopeful.

March 22, the patient was still doing well, pulse 78, temperature 98.7°, the stitches caused some pain and were removed.

March 24, improvement continued, the wound was looking healthy, the appetite was good and the patient was sleeping well. He was then considered out of danger, with the expectation that the drainage would afford relief to the cystitis.

The following additional report was received from Dr. Horsley, under date of April 4, 1890:

"Our case has progressed steadily and uninterruptedly towards recovery. We had no complications threatening the success of the operation at any time. The temperature never went higher than 100° F. The wound is now granulating nicely, and is about one inch in length. The urine is free from the tenacious muco-pus which was so abundant before and for a few days after the operation. I do not think it proper to allow the wound to close, as the prostate is still tender. Before closing the wound, I purpose having the patient let the urine accumulate in the bladder by wearing a rubber compress over the opening, and to try the outlet by the

urethra, so as to get a definite idea of the condition of the organ."

PNEUMONIA: WHAT IS IT?

(FOURTH PAPER.)

BY HIRAM CORSON, M. D.,
CONSHOHOCKEN, PA.

In my last paper several cases were introduced which were treated by our country, or, if preferred, village doctors. They were all spoken of as pneumonias, simple pneumonias. In the *University Medical Magazine*, April, 1890, a case is reported by W. Henry Price, M. D., as occurring in the University Hospital (service of Dr. William Pepper) which is called: "Pneumonia complicating Epidemic Influenza." The readers of the REPORTER will therefore please to bear in mind that every case reported by the Conshohocken physicians occurred during the prevalence of that same epidemic—*la grippe*—and were, as truly as Dr. Pepper's case, pneumonia complicating epidemic influenza. I say this in order to give my country brethren fair play—an even start; for I shall here give the Dr. Price case in full, word for word; and then let it be compared with those published in my third paper. Dr. Price writes:

"William A., aged 46, came to the Hospital, Jan. 7, with a well-marked case of influenza, showing the ordinary symptoms: head-ache, back-ache, pains in the limbs, lachrymation, coryza, and some cough with expectoration. Besides these, he complained of a 'stitch in the right side.' He was put immediately to bed, ordered *stimulants and tonics* (Italics mine), and a cotton jacket encircling the chest was applied, in addition to strong counter-irritation over the seat of pain. At this time auscultation gave a localized friction rub at the end of inspiration, and percussion showed impaired resonance over the same area. The pain continued, and antipyrin in five-grain doses, repeated thrice daily, was ordered, with considerable modification of his sufferings. The disease, however, spread upward, and friction râles became more diffused; but no exudation could be detected in any position of the patient."

"He now,"—we are not told when, on what day "now" refers to—"began to expectorate rusty sputum, although this was much less tenacious than that typical of pneumonia. Physical examination detected increased fremitus and bronchial breathing over the right upper lobe. At this time the temperature ranged about 103° to 104°; respirations were up to 48, and pulse rate 120. The next day he showed signs of circulatory embarrassment, and, although *cardiac and respiratory stimulants were pushed both by the stomach and hypodermically, he gradually sank and died on January 14, 1890.*" (Italics mine.) It would seem that as the man is dead and the treatment, such as it was, at an end, I might rest my case here; but no, the narration goes on; and I must go with it.

"The autopsy demonstrated the following points: Upon opening the pericardium the heart was found to be twice its normal size, mainly from over distention of all the cavities, which were filled with currant-jelly clots."—Clotted blood I suppose.—"Cardiac veins were also distended. The right heart and both venæ cavæ showed special engorgements. There was no change in muscle or valves, and no pericarditis. Right lung was completely consolidated throughout its upper lobe, which was entirely free from air and showed gray hepatization. The lower lobe showed spots of catarrhal pneumonia with still other regions of congestion. The middle lobe was entirely free from disease. All the lobes were highly adherent to each other from old pleurisy, and over the entire pleura was an exudation of fresh lymph. The left lung, together with all the other organs, were perfectly sound."

It is a comfort to me to have this case to compare with those of the country physicians who have reported their cases, which were in every way like this one, save that their patients were worse, and that they recovered, while this one died. They, like this man, were suffering from the prevailing epidemic, to which was added the congestion and inflammation of the lung to a high degree. They were indeed serious, most dangerous cases, but were promptly treated by the means which, in the practice of these physicians, had so often proved successful, that, despite the doubts and fears of the patient's friends, the responsibilities which confronted them and the knowledge that popular feeling was against their measures, and the leaders of the profession loud and unceasing against their plan of treatment, they asked for no consultants, but with a confidence created by numerous successes, used the best of all known means—free venesection—to relieve their suffering patients from the engorge-

ment of the lungs which was suffocating them.

Drs. George B. Wood and Bartine have graphically described the distention of the blood-vessels and especially those minute arterial terminations called capillaries. Whenever my mind turns to the consideration of the congested and inflamed lung, I can see no relief for it, save by unloading these vessels by venesection. Can it be done by antipyrin, or by arterial sedatives to hold the pulse below eighty, as taught by Dr. Bartine? Or by stimulants—the name for doses of brandy or whiskey, as used in Dr. Price's, or, rather, Professor Pepper's case—when "pushed" and used hypodermically? To these questions I might say No; but I prefer to give, as an answer, the apt illustration which was given by Professor Samuel D. Gross in a discussion on this subject, in the Pennsylvania State Medical Society, at Easton, some years ago. I once used it in a former paper; but it is so true and convincing that it will bear repeating, especially as many readers of the REPORTER have never heard it. Professor Gross said: "Should a man have a congestion and incipient inflammation of the conjunctiva, so that the sclerotic coat would show an intense redness, and the patient was then bled, while in an erect posture or sitting on a chair, until there was an approach to syncope, the redness would disappear; the capillaries being emptied of the blood which had distended them. Just in the same manner would the capillaries of the lungs be relieved, and, in a case of pneumonia the increased action of the heart be modified." Two valuable results from one of the safest and most pleasant remedies, followed by no pain or sickness or unpleaaant effect on the brain or nerves, as is caused by almost any medicine in an efficient dose. Dr. Gross continued: "The exhibition of tincture of veratria or tincture of aconite in a dose to reduce the frequency of the pulse much below the normal rate, would produce no change in the appearance of the eye-balls, as the capillaries would not be unloaded by the mere slowing of the pulse."

It seems to me that just now and here is a proper time and place to call attention to a most important consideration: one that does not appear to have been regarded as of any consequence by the uses of arterial sedatives. I allude to the slowness of its action, when prompt relief is the only safety. In every case presented by the Conshohocken doctors, they, on seeing the patient oppressed and embarrassed in breathing by the congestion of the lung, realized that there should be no delay in applying their means of relief; and, expert as I know they are in the use of the lancet, the blood was spouting from the median basilic vein in less than ten minutes, and the patient experienced, as the blood was flowing, a sense of relief which increased as the blood continued to flow. I have rarely bled a person thus oppressed in pneumonia, who has not in a few minutes after the operation spoken of the relief obtained by it.

Now, I want the attention of the reader. Not one of these three physicians would have been willing to leave his patient until the next day without bleeding him. No, not for a single hour; knowing full well that such absence would seal the patient's fate. You ask, "Why is this haste necessary? Are there not very great congestions and intense inflammations which do not terminate fatally, though not treated by blood-letting? which even go on to suppuration, and yet the patient survive: notably, mammary inflammation in females?" Yes; and this may serve me well to show why in this case—mammary abscess—the treatment by arterial sedatives or waiting for a crisis may be continued from day to day, and life be not even threatened; because, although it is *on* the chest, it is not *inside* of the chest, distending the blood-vessels and the minutest capillaries, and blocking up the air cells, so that the patient is threatened with suffocation if not relieved. How utterly useless these arterial sedatives are even in mastitis, we all know. But they serve to make the patient believe something is being done for her. I have conversed with many persons who rely on these medicines, and have found that they generally use doses which have to be repeated every two or three hours for a whole day, indeed oft-times much longer before the medicinal, or rather poisonous, effect is produced. This waste of time waiting for its action is of little moment in mastitis and many other inflammations in parts of the body not necessary to the continuance of life; but when the brain, the heart or the lungs are attacked there should be no talk of tendencies to recover, no waiting for a crisis, no dependence on the let-alone doctrine; but an energetic use should be made of efficient means of cure. Should a patient, fairly under way with pneumonia, be treated by a reformer,

and wait hours upon hours for the slow action of his remedies, the congestion and inflammation rapidly increasing, and with their increase his sufferings becoming more and more intolerable—and there are few conditions harder to bear than the struggles for breath—he would soon be beyond the possibility of recovery. The mammary gland may be allowed to suppurate or be cut away by the surgeon and life not be endangered; but the blocked-up lung must be relieved before the suppurative process is reached or death is almost, if not wholly, inevitable. Dr. George B. Wood has told us that it is doubted whether recovery ever takes place in the third or suppurative stage.

I have been tedious in presenting the importance of prompt action with efficient measures, and the danger of the inevitable delay which accompanies and is inherent in the methods of treatment, followed by the "arterial sedative," "waiting for crisis," do-nothing people called reformers.

But I did my best; and it has been well said:

> "Who does the best his circumstance allows,
> Does well; acts nobly; angels can no more."

Let us now return to Dr. Pepper's case. The patient was a man aged 46 and in the prime of life; every organ in his body was sound and performing its functions properly, save only the right lung, which was moderately affected in its lining membrane, as was common with hosts of people during the time of the epidemic, *la grippe*. There was, too, a "stitch" in the side and a general malaise such as accompanied the recent influenza, and "some cough and expectoration." "He was immediately put to bed, ordered stimulants and tonics, a cotton jacket, and strong counter irritation over the seat of pain." I am truly thankful to have this case. The hospital physicians had it in its early, remediable stage; and it was under the care of the great leader—or one of the leaders—of the medical profession in the United States; and to his teachings and treatment the hosts of practitioners who denounce blood-letting in all diseases look for guidance. Well, then, what did he do for this sick stranger? At once he "ordered him stimulants"—whiskey or brandy, no doubt—and "tonics"—quinine certainly. He should have told the readers of the *University Medical Magazine* why he ordered this treatment; should have given some good, convincing reason for it. He should have told the students, and also the readers, what was going on inside of the chest; what caused "the stitch in the side, the cough and expectoration," and that the remedies which he ordered were adapted to the removal of these diseased conditions. An experienced physician like the one who had charge should surely have known that there was some bronchial affection; and the stitch in the side should have been to him an indication that there was mischief being enacted in the lung or the pleura. Believing these conditions to exist, were stimulants—alcoholic stimulants—needed? How did he expect them to act, so as to bring relief to his patient? Were they not, by their well-known mode of action on the human system, positively interdicted, because of the almost certainty that they would increase the inflammation in the bronchi and the lung tissue?

But what are the facts? Despite the stimulants "the pain continued." What a stubborn kind of pain it must have been, not to yield the field to stimulants! It seems to have had no reverence for whiskey. But the physician was not to be baffled. He earnestly and determinedly engaged in battle with the disease, and prescribed his most potent remedy for "stitch in the side": the celebrated, but wayward antipyrin, in five-grain doses, three times daily. That is, a dose about every six waking hours, which allows the disease an open, unobstructed way before it, to seize on more of the lung. The morning dose has been given—the patient feels no relief, but waits and suffers for six hours more; then comes a second dose, but still no relief; and again six hours of suffering and waiting for the third dose. How many days this went on we are not told; but until the *doctor* thought there "was considerable modification of the suffering." But what was the patient's real condition? Listen to the doctor: "The disease, however, spread upward, and friction râles became more diffused;" in spite of the "considerable modification," I suppose. "He now began to expectorate rusty sputum." Poor fellow! While the doctor was waiting in vain, day after day, for good effects from stimulants and antipyrin, and despite a seeming or fancied modification of your sufferings, pneumonia was rapidly developing, indeed had fully developed; for, in the doctor's words: "At this time the temperature ranged about 103° to 104°, respirations up to 48, and pulse rate 120." (Oh, that a

Conshohocken doctor could then have been at your bedside !)

We are not told what was done that day ; but from what follows we are justified in believing that the administration of stimulants was continued with increased force, for the narrative thus proceeds : "The next day he showed signs of circulatory embarrassment" (which means, I suppose, that the man was greatly oppressed, the heart laboring vainly to keep the right side open to receive the blood from the two great veins which were crowding it upon that organ) and, although cardiac and respiratory stimulants were *pushed* both by the stomach and hypodermically, he gradually sank and died on January 14, 1890."

Such was the treatment of a case as favorable for recovery, under such treatment as our country doctors gave to their patients, as ever occurs. The autopsy showed that every organ of the body was perfectly normal, save the right lung ; and of that only the uppermost lobe was affected with pneumonia, besides a few spots of catarrhal pneumonia, and other regions of congestion in the lower lobe. The middle lobe was entirely free from disease. The left lung, with all the other organs, was perfectly normal. There was no disease of the muscles or valves of the heart—no pericarditis. The man died from an uncomplicated pneumonia of merely one lobe of the right lung. No, I cannot say that ; I fear the stimulants and quinine and antipyrin helped the disease. Behold the condition of the heart ! "Twice its normal size," mainly from over distention of all the cavities, which were filled with currant-jelly clots. "The right heart and both venæ cavæ showed special engorgements. Cardiac veins were also distended." What caused the heart to be in this condition ? Not loss of blood, I ween. I dislike to dwell on this case : one of the most favorable for treatment, and which came under the notice of the physician in its earliest stage. Lay it alongside of the Conshohocken cases, and see how much worse every one of them was when the blood-letting was resorted to ; see the relief it brought, and the fact that the patients were saved. One word more in condemnation of beginning the treatment of such a case with stimulants and persisting in their use, and increasing and "pushing" them, day after day, until the heart, distended almost to bursting, gave up the struggle against doses of alcoholic liquors, pushed with increased force as its contractions failed. What a sad picture ! a man suffocating ; a heart filled with currant jelly clots which have blocked up its every cavity, after distending it until it could be enlarged no more—still having stimulants poured down his throat and injected under his skin ! And for what ? Tell us why it was done, or forever cease denunciations against blood-letting.

Professor Samuel D. Gross was a strong advocate for blood-letting in pneumonia. His address before the American Medical Association is a grand appeal for its use ; and, in a paper published (I think) in the *County Practitioner*, he wished that his voice in its favor "could re-echo to the ends of the earth." His son, ill with pneumonia, died without receiving the benefit of that means of cure. Many years ago Professor Joseph Carson, M. D., said that Dr. Ezra Michener was one of the best practitioners and writers of medical papers in our State. No stronger advocate for the use of the lancet in pneumonia and some other affections was known anywhere, even to the day of his death, which occurred only about ten years ago, when he was 92 or 93 years old. When he was in his 87th year he fell and broke his humerus near its upper end. "Five days afterwards he felt quite poorly and chilly, with aching pains in the maxillary glands, in the afternoon ; in the following night he awoke with fever, with weight and a burning sensation in the right thorax ; the breathing was oppressed and hurried." Dr. Stubbs, who was called to him, diagnosticated pneumonia ; but doubted whether it would be safe to bleed him on account of his great age. Dr. Michener said : "It must be done. If I have but a little blood in store, a proportionate quantity should afford relief, especially now in the congestive stage." What confidence in the remedy, which he had used successfully hundreds of times ! He said : "I will sit up, a less quantity of blood will suffice." Dr. Stubbs bled him ; and when he drew his first free breath, the flow was stopped. Fifteen ounces had been taken from this thin, spare, old man ; and the relief was perfect. Dr. Stubbs, in his report, says : "If bleeding will do this for a thin, spare man of his age, what ought we to expect from its use in young and plethoric subjects ?" And, let me add, what might we expect in a man 46 years of age, sound in every organ of his body save one lobe of one lung ? Contrast the treatment confided in by this old man, with an experience reaching from 1816 to 1881,

with the hospital case. In the one there was immediate relief by the means used, in the other a steady increase of suffering and finally death in seven days.

It is matter of regret to me that necessity demanded these papers. I have seemed to make the two great medical schools of Philadelphia special points of attack. Circumstances favored this; and it was appropriate; for they are the leading medical colleges and hospitals of America; and their teachings and practice are received as medical gospel in every college and hospital in all our vast country. A reform there would be the prelude to reform in all.

In view of my advanced age, it is not probable that I shall ever address the readers of the REPORTER again on this subject. These papers have been written in sorrow, not in anger. I claim for myself no exceptional goodness; have no faith in cold and formal prayer; have never reached that humble state in which I could "turn the other cheek" to the smiter; yet as regards those who persist in a most erroneous and dangerous treatment of pneumonia, and denounce the means so successfully employed by the profession for more than a century, I have often desired to make my own that beautiful appeal which has come down to us through almost nineteen centuries, as redolent as when first uttered of mercy, charity and forgiveness: "Father, forgive them, they know not what they do."

SYRUP HYDRIODIC ACID *vs.* ALKALINE IODIDES.

BY A. E. NORTON, A. M., M. D.,
PHILADELPHIA.

Our attention, in practice, is being constantly directed to the fact that the iodides of the alkalies are exceedingly repugnant, not to say nauseating and irritant forms for the internal administration of that valuable alterative and antiseptic, iodine.

We have had much difficulty in administering iodide of potash in cases where its use should be prolonged; not only on account of its direct irritant action, but also by reason of its destructive influences upon the gastric secretions; the caustic alkali neutralizing the natural acids of the stomach, thus causing anexoria and other evil symptoms.

We have repeatedly attempted to mask the bad properties of iodide of potash by using it in conjunction with various vehicles, but with only limited success. Women and children, usually, greatly dislike any mixture containing the potassium salt, and a delicate stomach will seldom retain sufficient to produce beneficial results. For a number of years past I have used as a substitute for the alkaline iodides, iodide of hydrogen or hydriodic acid, in a syrupy form; and where I have found it necessary to place the system under the influence of iodine, or wherever that element was indicated internally, I have never found any form of iodine to give the prompt and satisfactory results that I have obtained from the use of this admirable preparation. But before speaking further of this iodine compound I wish to show why the alkaline iodides are objectionable as means for administering the element in question.

In my opinion, which is substantially the same as that of many other physicians, potassium iodide, the most frequently prescribed salt of iodine, is the least desirable of all the iodides of the alkalies. It is more apt to irritate the mucous coating of the stomach than either the ammonium or sodium iodides, and it cannot be so freely given as either of the latter salts; nor can the medication be so long continued. When we come to subject these drugs to an analysis, the reason for this difference is so apparent that one is not required to be well versed in chemistry to discern it. I will attempt to demonstrate:

The equivalence or combining power of iodine being 127 and that of potassium 39.7, they naturally unite in that proportion to produce potassium iodide, and the finished salt, as we find it on the market, contains 24 per cent. of its alkaline constituent —potassium. This large amount of alkali more than neutralizes the natural acids of the stomach, causing nausea, loss of appetite, etc. The sodium salt is frequently resorted to on account of its lesser tendency to irritate; but from the fact of its also containing a very large percentage of the alkaline salt, sodium (the combining power of sodium being 23), it is open to the same objections that are found with the potassium salt, though perhaps its pernicious effects are less frequently observed.

Ammonium iodide is thought by some to possess certain advantages over either of the above salts of iodine; but it also contains a

large amount of alkaline salt, as a carrier for the iodine; and, in addition, is rarely found on the market uncontaminated with iodate and other impurities which render it objectionable.

The syrup of hydrogen iodide or hydriodic acid, however, seems to me to be, theoretically and practically, the ideal form of iodine, inasmuch as it is as palatable as an elixir, having a gratefully acid taste, being perfectly colorless and beautiful in appearance.

Twenty years ago the fact of a medicinal product being handsome in appearance and appealing pleasantly to the palate would probably, of itself, bear little weight; but in the present epoch of elegant pharmacy, when the tastes of the people are educated to pleasant remedies, the agreeableness of a medicinal preparation, when accompanied by merit, necessarily furnishes one of the strongest incentives for its adoption.

In hydriodic acid the element hydrogen, which is used to combine with iodine in the formation of hydrogen iodide, is gaseous, and, being a monad element, its equivalence is but one; it therefore unites with iodine, also a monad element, having the atomic weight one hundred and twenty-seven. It will readily be observed that the two elements unite in the direct ratio of 1 (hydrogen) to 127 (iodine) and here, at the very foundation of the preparation, is where the perfection of the compound is seen to advantage. It will be observed that the carrying, the basilous element, hydrogen, is represented in a quantity less than 1 per cent. Contrast this formula with that of iodide of potash, containing 24 per cent. of caustic and irritant alkali as a carrier for its equivalence of iodine. Contrast it with any other form of iodine now in general use, and from every point of observation the advantages will be found in favor of hydrogen iodide.

I have found the syrup more assimilable than other forms of iodine, and account for the fact thus: When an alkaline iodide is placed in the stomach, its alkaline constituent unites with the free hydrochloric acid found there, and by the following reaction produces hydriodic acid:

$$HCl+KI=KCl+HI.$$

Certainly the amount of hydrochloric acid found in the stomach is very small, but the fact that it unites with the potash of potassium iodide, with the above result, is beyond a doubt; and as nature supplies additional quantities of hydrochloric acid, it continues to unite with the potassium salt in the above manner, until all available salt is converted. While this is going on the hydrochloric acid, so needful for digestion of food, is being appropriated for other purposes; thus the general upheaval of the stomach, frequently met with when administering the alkaline iodides is evinced by nausea, eruptions on the skin, etc.

When iodine is administered in the form of hydriodic acid it is already prepared for assimilation, and being in itself slightly acid, robs the stomach of none of its necessary constituents, and therefore no evil effects are observed. In the practical use of the preparation I have found it to possess but one disadvantage, and that one not very serious. It consists of its incompatibility with some of the metallic salts, though combinations may be made with vegetable tinctures and fluid extracts, or with bichloride of mercury, which latter drug I frequently combine with the syrup hydriodic acid, the combination producing the same familiar reaction which is observed when iodide of potash and the bichloride were brought in contact, viz.: biniodide or red iodide of mercury, which is redissolved by an excessive quantity of the iodine compound. I have frequently prescribed the syrup of hydriodic acid in conjunction with arsenic and its preparations, particularly Fowler's solution, and have noted excellent results where this form of medication seems indicated.

Hydriodic acid is by no means a "new remedy," though its use has been limited on account of its extreme delicacy, as usually prepared.

The dose of the syrup, speaking from my own observations, is from a few minims to half an ounce, and the same should be highly diluted with water. One teaspoonful of the syrup is equal in therapeutic strength to about five grains iodide of potash. Fifteen-minim doses, frequently repeated, will give prompt relief in bronchial and asthmatic difficulties. In psoriasis; enlargements of the thyroid gland, and other glandular enlargements; in syphilis; spinal sclerosis, etc., the dose employed should be from one to two teaspoonfuls, three times daily, preferably at meal-time.

I think if those of my professional brethren who feel the want of a particularly fine iodine preparation, will give the syrup of hydriodic acid a trial, they will find it all

that could be desired. I, personally, consider it a *sine qua non.*

A CASE OF DETACHMENT OF THE ALVEOLUS AFTER EXTRACTION OF THE TEETH.

BY C. H. M. NEALL, M. D., D. D. S.,
PHILADELPHIA.

A patient called at my office to have eight teeth extracted, with the roots of the first and second molars of the upper jaw. After extracting the two centrals, two laterals, and the canine of the right side, the alveolar process became detached and came down to the extent of half an inch. I used my excising forceps and cut through the alveolus in extracting the roots of the first and second molars to loosen them so as not to cause any more displacement than what already existed. After finishing the extraction of the teeth, I forced the alveolar process back into its normal position by firm pressure, and adjusted a piece of cork to fit the alveolus perfectly. The cork contained a number or holes, to allow of free drainage in case of any discharge, and I treated case antiseptically. The cork was held in place by means of a "roller bandage" closing the jaws. The patient received all nourishment by means of a glass tube. The antiseptic mouthwash contained ten drops of carbolic acid to the fluid ounce of water. In three days the patient returned to my office and I removed all the dressings, finding everything doing very nicely. In about twelve weeks she returned, the process firmly healed, and I took an impression of her mouth, and made a full upper denture.

This is the first case that has come under my observation, but I have heard of other cases similar to mine.

While writing of this case for medical men, to whom an accident of the sort would be more embarrassing than to one who makes a specialty of dentistry, I would like to add a word in regard to the importance of some knowledge of dental medicine to all physicians and especially to those who practice in the country. Many physicians are so situated that it is necessary for them to extract teeth comparatively often, and usually they have to perform this duty with an altogether insufficient preparation for it.

Numbers of teeth attempted to be extracted are fractured just through the inability of the physician to decide what kinds and forms of forceps to use.

I believe that all medical schools should devote time to a careful study of the teeth as well as to the other branches of medicine, and have demonstrations on patients in the clinic, so that students can see for themselves what forceps are used, and how they should be applied.

Reports of Clinics.

WOMAN'S HOSPITAL, PHILADELPHIA.

SURGICAL CLINIC.—PROF. JOHN B. ROBERTS.

Scapular Abscess.

James B., 7 years old, colored, entered the Hospital Nov. 5, 1889, suffering from an abscess over the shoulder-blade. The abscess was tubercular, and about the size of a man's fist. On entrance, the patient's temperature was 103.5°, his pulse 102, and his respiration 33 per minute. The child was emaciated, had a hot, dry skin, and parched lips. The shoulder was stiff, and painful when movement was attempted. The patient was etherized and the abscess was freely opened, and, after its evacuation, well curetted. A drainage-tube was then inserted, and the wound closed. Dry antiseptic dressings were applied, and the shoulder and arm immobilized.

Tenosuture of Radial Extensor Tendons.

Three years before the boy had sustained an injury of the left wrist by being cut with an axe across the radial side of the wrist; whereby the extensor tendons of the thumb, and the tendons of the extensores carpi radialis longior and brevior, were divided. The wound had been sewed up and allowed to heal, without the surgeon having united the several tendons, and the child now suffered from traumatic wrist-drop, being totally unable to extend the radial side of wrist and the thumb. After the abscess upon the shoulder had sufficiently healed, Dr. Roberts had him etherized in order to correct the deformity of the hand. A longitudinal incision was made in the direction of the tendons, and the severed ends of the

extensores carpi radialis longior and brevior were found and stitched together. The operation was tedious, because by this time the upper ends, which had retracted at the time of the injury, had become agglutinated with the surrounding tissue in the vicinity of the annular ligament, and it was difficult to distinguish them until the tendons had been found above and followed downwards. The distal ends of the tendons were only discovered by knowing their attachment to the metacarpal bones of the index and middle fingers, because they had become atrophied and appeared as small portions of fibrous tissue. Pulling on them, however, extended the wrist and established their identity. Only a union of the extensors of the wrist was attempted; as in a child of seven years the thumb tendons are so small that after three years atrophy it would be almost impossible to find them, and, therefore, it was deemed wise not to prolong the already protracted operation. Chromicized catgut was used to suture the ends of the tendons together, which were overlapped and held by passing the suture through each and twice before tying. The wound was then sewed up, dressed with dry antiseptic gauze, and the hand kept in a position of over-extension by a plaster of Paris dressing over all, so as to prevent dragging upon the re-united tendons. The temperature after the operation at no time rose to 102°, and after the first two days fell nearly to normal, and remained there. On December 6, two weeks after operation, the dressing was removed and the wound found nicely healed, except at one place, where there was a small quantity of pus. This pus was supposed to be due to the tuberculous character of the child's system, and not to failure in the antiseptic precautions used; although this was not certainly established. The wrist was washed with bichloride solution, and antiseptic gauze re-applied, and the forearm placed upon a straight splint. It was dressed again on December 14, and after that daily until all parts were thoroughly united. On December 21, the splint was discontinued, and after the swelling of the fingers had completely subsided, the patient was found to have very fair use of the fingers and hand. At the present time there is almost perfect return of extension to the wrist, and the hand has accordingly become a much more useful member. It is possible that at a future time an attempt may be made to find and unite the small thumb extensors. The case well illustrates the importance of sewing all cut tendons at the time that incised wounds are presented for treatment. It is a common practice for physicians to be satisfied with simply suturing the cutaneous wound. This is a reprehensible practice, since it leaves the patient with a disabled member. All cut structures whether muscles, tendons, nerves or fasciæ, should be subject to immediate suture with buried catgut or silk sutures. The surgeon's duty is not done unless this is accomplished. Secondary suture as in the present case is valuable when primary suture has been neglected.

Operation for Club-Foot.

Katy F., a child eleven years old, was admitted to the Woman's Hospital, Nov. 13, 1889, for an operation for congenital club-foot on the left side. The child was said always to have been rather delicate, and at the time of admission, was still somewhat anemic, although otherwise in good condition. The deformity was of the variety talipes varus, and she walked, with great difficulty, upon the outer border and dorsum of the foot, where a large bursa had developed. Five years before admission, she had been an inmate of the Children's Hospital for operation on the same foot, and at that time several tendons, it is said, were cut and apparatus applied to correct the deformity, but without success. Her present age, eleven years, made Dr. Roberts decide, that anything short of a thoroughly radical operation would be useless, as, by this time, the bones of her foot had so far ossified, as to give no hope that they could be molded into proper shape by any apparatus, and his plan was, therefore, to remove such bones of the tarsus as prevented the foot from being brought into proper position. Tarsectomy was accordingly performed Nov. 15, 1889. The bones of the tarsus had been distorted until they formed a wedge, the outer ones being the broad end of the wedge, and those on the inner side of the foot forming the apex.

A large flap was cut upon the outer side of the foot, and the cuboid bone first removed, then the external cuneiform bone and the scaphoid, and, as the foot would still not come rightly into place, a projecting portion of the os calcis was also cut off with the bone nippers. There was considerable oozing, most of which seemed to come from the cut surface of the os calcis. The plantar fascia was then freely divided as well as

the tendon of the tibialis anticus, and the foot forcibly bent into position. A drainage-tube was inserted, dry antiseptic dressings were applied, and over all a plaster of Paris bandage to keep the foot in position, until the parts had become firm, and the wound had healed. After the operation the child was very nervous, and her temperature ran up for a couple of days, reaching even so high as 105.2°; but it soon came down to nearly normal, and remained there during the rest of her stay in the hospital. The oozing was so great also, that within the first twenty-four hours, all dressings had to be removed, because they were soaked through. The limb was washed with bichloride solution (1-1000), the drainage-tube removed, and fresh dressings applied and covered with a strong gypsum bandage to retain the foot in proper position. This dressing remained in place till December 20, a period of about five weeks, when it was again changed. At this time the wound was found to be healed except at one small point. It was now dressed daily with carbolized zinc ointment, and by December 26, was completely healed. All dressings were discontinued, and the Faradic current applied to the muscles of the leg for ten minutes twice daily; and massage of the foot and leg given for half an hour, as often. By degrees the patient began to walk, taking only a few steps at first, until by December 31, she had acquired good use of her limb. She now stands firmly upon the sole of her foot, which is shorter than the other because of the loss of the tarsal bones, and the long standing atrophy from disuse. She can walk very well, with only a slight limp. She needs simply a well-laced firm shoe, with, possibly, a steel rod at each side of the ankle-joint, to support the weak foot and ankle until the parts become more solid and stronger. Her gait will not have the elasticity of a child with perfectly normal feet; but the limp will be almost unnoticeable when she grows older and becomes accustomed to walking.

Leper Hospitals in India.—It is stated that, to commemorate Prince Albert Victor's visit to India, Sir Dinshaw Petit has offered one lakh of rupees to build a Leper Home for Bombay, and the Nawab Junaghad has promised to build a Leper Asylum for the province of Kattywar. The permanent Memorial Fund for a Leper Asylum at Calcutta amounts to upwards of 45,000 rupees.

Periscope.

Pneumothorax.

Mr. Walter A. E. Waller reports the following interesting case of pneumothorax in the *Lancet*, Feb. 8, 1890, in an apparently healthy young man without realized injury:

The patient, sixteen years old, had never been laid up, except for an attack of rheumatic fever nine months before. During this attack there was a mitral bruit, with very thumping action; but this all cleared up, and when examined for admission into a lodge of Foresters a month or so previously to his present illness he was found sound. On April 19, 1889, being in his usual health, he went out brook-jumping in thin shoes, but did not get wet, and had no fall. After this he had a cold in the head, but nothing more. On April 24 he began to ail, aching all over, etc., but walked a mile and a half, with a steep hill each way. On the following day pain and fulness in the epigastrium were experienced, with short breath; but he walked to work, though having to rest twice in going up the hill. On April 26 he got up and walked into Rugby, but was so ill when he reached his work that he was soon sent home in a cab. Next day Mr. Waller saw him at his house. He did not look ill, and talked of going to work again in two days. His temperature was normal. On examining the patient's chest, inspection showed deficient movement of the right side of the chest, and auscultation revealed insufficient respiratory sound on that side, though the breathing was nowhere inaudible. No tube sounds and no egophony were present, but there was a most peculiar and marked metallic echo over the front and back of the right side on coughing or speaking, and it did not seem that liquid was concerned in its production. Resonance all over the right chest was a little deficient, but fremitus was everywhere present. On the next day the patient was in bed, with a temperature of 101°, but there was no pain. Next day, however, he was unable to sleep from violent pain situated low down and in front of the right chest. Physical signs were much the same. No friction sound to account for pain. The right chest was now rather more resonant than the left. Movement and respiration were more deficient. The curious metallic echo was as marked as before, and could now be produced by deep inspiration, as well as by coughing and speaking. The tempera-

ture was 102°. The pain was much relieved by poultices and small doses of morphia. The tongue was thickly coated; there was some colorless, frothy and muco-purulent expectoration. On the 30th the temperature was 101.6°, pulse 120 at least (weak), and general restlessness was marked. The breathing was very embarrassed, face ruddy, and the ears were becoming blue in color. The right chest was fuller both above the clavicle and over the general surface; tongue was still thickly coated. The patient experienced great thirst.

A diagnosis of uncomplicated pneumothorax, probably of traumatic origin, was reached, and stimulant expectorants with opium and digitalis, brandy when necessary, were given. The day following the bowels were relieved after a good purge, and there was no alteration in the pulse. The patient slept two hours in the early part of the night. Chest signs much the same, with less expectoration. Mr. Waller made an exploratory puncture in the axillary line, but the needle soon got blocked, and was withdrawn. On May 2 the patient slept a little. Pain distinctly paroxysmal in character round the right nipple. He was still able to expectorate some sputum with effort; movement of the chest was freer, but it had the appearance of having air under the skin. He complained greatly of oppression over the epigastrium. Mr. Waller punctured the right chest with an ordinary hydrocele trocar; plenty of air was forced out, but no fluid. The patient passed a good night, and slept about five hours, and had no pain or dyspnœa till the morning, when the metallic echo was not so distinct in the axilla, though much as before elsewhere. After this the patient's recovery was rapid and, although the physical signs did not entirely disappear, he was soon able to go to work again.

Olive Oil in the Treatment of Gall-Stones.

When, some years ago, some cases of successful evacuation of gall-stones in attacks of biliary colic following the ingestion of large quantities of olive oil were published, they were received with some incredulity, which passed into ridicule when it was found that the oil itself was evacuated in the form of saponified pellets. Nevertheless, the practice was not abandoned in some quarters, and from time to time further successes were claimed for this singular form of medication. Recently Dr. Rosenberg has related three such cases, which are quoted in the *Lancet*, March 1, 1890. The first was a patient, thirty-six years old, who had suffered from gall-stone for several years and had been treated without result. The gall-bladder was enlarged. The patient during two weeks drank over a quart of olive oil, only vomiting once, and at the end of that period the liver and gall-bladder had notably diminished in volume. She had remained free from colic eighteen months after the treatment. The second case was that of a workingwoman, thirty-seven years old, who was attacked with biliary colic. There was slight icterus, which always increased at the menstrual periods. The liver reached for three fingers' breadths below the ribs. She was given seven fluid ounces of the oil mixed with a little menthol and the yolk of egg. Next day the pains had disappeared and the liver had diminished in size. The jaundice and pruritus persisted; so another similar dose was administered, when these signs also disappeared. For several days after she passed biliary calculi. The like result was obtained in a third patient, thirty-eight years old, who, after nine years' suffering from attacks of hepatic colic, had been unrelieved by many "cures" at Marienbad and Carlsbad, although on each occasion she had passed some small calculi. Rosenberg states that of twenty-one cases treated on this plan there were only two in which it failed. He found by experiment that large doses of olive oil increase considerably the flow of bile and diminish its consistence. And he mentions, on the authority of Cantani, that in Italy, where olive oil is taken largely as an article of diet, gall-stone is less frequent than in any other country. Lastly, Rosenberg would not advise recourse to this remedy until other methods had been tried and failed; but, as he truly says, it may well be prescribed before advising recourse to cholecystotomy.

The value of olive oil in the treatment has also been recognized by several physicians in the United States. In the Reporter, Nov. 9, 1889, Dr. Thomas J. Mays reported three cases of gall-stone in which desertspoonful doses of olive oil, exhibited every three or four hours, completely relieved the hepatic colic and caused a rapid subsidence of the enlarged gall-bladder. In the Reporter for March 1, 1890, a case reported by Dr. J. I. Kelly was quoted, in

which two doses of olive oil, one of eight fluid ounces and one of six fluid ounces, given two hours after, caused the immediate relief of a most severe attack of gall-stone colic, and was followed by the passage of a handful of gall-stones the same day.

Hypnotism and the Law in Austria.

In October, 1889, the following law, relative to hypnotism, was promulgated in Austria:

"Whosoever, for the sake of the healing of disease, the prevention or mitigation of pain; or for the sake of instruction, experiment, demonstration or exhibition, shall use any method which is calculated to cause the loss of, or weaken, the consciousness of a human being, or which shall lessen the said human being's mental activity, shall be punishable with imprisonment, or a fine not exceeding 300 florins."

At that time the *Wiener Med. Presse*, in commenting upon the propriety of such a law, claimed that it could not be extended to the use of hypnotism by physicians without also including the use of other means capable of producing unconsciousness, or narcosis, such as morphine. The views of the Chief Sanitary Councilor (Oberster Sanitätsrath) agree with the above. In bringing the matter to the attention of the Department of Justice, he says, special enactments by which the study of hypnotic phenomena, or the use of hypnotism for therapeutic purposes would be restricted or made liable to punishment, are neither justifiable or necessary, because the study and therapeutic use of hypnotism by physicians could no more be denied them or restricted, than the use of narcotics or any other heroic remedies, such as poisonous drugs; and further, because misuse of the privilege of employing hypnotism, or neglect of proper precautions when it is employed, is not a specific offense, and is covered by the same penal statutes which apply to the offenses of physicians.

Antipyrin in Asthma.

Mr. Charles Smith reports, in the *London Medical Chronicle*, March, 1890, the case of a man, aged thirty-six, who had suffered from asthma for some years, the attacks commencing shortly after measles. The season of the year had no influence on the ailment, the paroxysms being as frequent in summer as in winter, but the time of taking food of course had a marked influence on them. Treatment for the purpose of preventing the asthmatic attacks entirely failed, but nitrite of amyl at first seemed to shorten them. Usually they came on every month or six weeks.

In August, 1889, thirty grains of antipyrin were given at the commencement of a paroxysm. In ten minutes complete relief was obtained. Twenty-four hours after there was a slight recurrence of the attack, which antipyrin promptly subdued. From that time to January, 1890, there had been no recurrence of the attacks.

Psilosis, or Sprue.

Dr. C. Begg, in the *Lancet*, Feb. 8, 1890, in writing on the intestinal disorder variously named "psilosis" or "sprue," which is common in China, from his nine years' medical experience in that country, points out that there is little ground for believing the affection to be a specific disorder of the intestinal mucous membrane, as urged by some writers. He would rather regard it as a form of intractable diarrhœa from deranged intestinal digestion; and, in support of his contention, he points to the fact that the tongue remains clean and the appetite unimpaired. His main arguments are, however, derived from the result of treatment, for he finds in santonin a drug which acts as effectually in such cases as ipecacuanha does in dysentery. He was led to employ santonin from suspecting the presence of ascaris lumbricordes as a cause of the diarrhœal symptoms; but, although in no case was this parasite met with, the drug had a remarkable effect in restoring a healthy state to the bowels. His view is, that "sprue" is due to the action of a microbic parasite upon the products of digestion, which, being altered and rendered unfit for absorption, act as irritants to the intestine and cause the intractable diarrhœa; and, in support of this view, he quotes Dr. Thin (who, however, regards the affection as due to a condition of the mucous membrane, which ultimately passes into atrophy), who describes several kinds of organisms in the fluid motions, notably a special form of bacillus. The value of santonin in other than cases of intestinal worms could not be better shown, a dose of five grains (for adults) once daily sufficing to cure the diarrhœa in a few days.

The sprue, as met with among the foreign

residents of China, is almost unknown in this country. There, however, it is greatly dreaded; many physicians claiming that nothing but an entire change of climate will effect a cure. Fatal cases occur frequently. The term "sprue" as defined by Dunglison, signifies "trush" and is usually applied to the common aphthæ of children. The name has been incorrectly applied to the disease in China for the reason that the latter frequently begins with symptoms of stomatitis.

Union of Tendons by Sutures.

At a recent meeting of the Surgical Society of Vienna, Dr. Schüssler showed five patients from Billroth's "Klinik" where section of the tendons had been successfully united by stitches. During the year thirty of these cases had been operated upon. In searching for the cut end of the tendon it is recommended that a longitudinal cut of the skin should be made in the direction of the tendon, so that the cicatrix of the skin may not become involved in the union of the tendon, as the movement of the limb may thus become impeded. In all these cases passive movement was commenced between the third and fourth week, although the perfect healing took months. Prof. Dittel remarked that the history of these operations was interesting, and not of recent origin. Heister, in the year 1750, wrote a small treatise on the union of tendons by sutures, in which he has described several methods. Prof. Billroth expressed his entire satisfaction with the happy results in these cases, which were principally due to the antiseptic treatment. Before antiseptics the wounding of tendons was a serious matter, as pyemia or other blood poisoning was not uncommon. But even yet in favorable cases there always remains a thick, hard cicatrix which prevents the free movement of the muscle.—*Medical Press and Circular*, Feb. 12, 1890.

Study and Examinations in Germany.

In a recent lecture by Dr. A. W. Schüddekopf, on "Universities and University Life in Germany," he said that the German student is much less frequently examined than his English brother; but then what an ordeal when it comes! Unlike the English system there is little or no paper work, the candidate being examined *vivâ voce*, more importance being attached to the grasp he shows of his subject and his manner of manipulating it, than to his knowledge of facts. Besides the *vivâ voce*, candidates have to write one or several "dissertations," which may take many months to prepare. Dr. Schüddekopf reminded his audience that, in Germany, University degrees are not considered to qualify candidates for masterships, for a license to practice medicine, and other offices, except in the case of candidates for a University professorship; but that candidates for such offices must have passed the "Staatsexamen," which in most cases is much more difficult than the degree examinations. Relating his own experiences in passing his "Staatsexamen," Dr. Schüddekopf caused a tremor to run through a sympathetic audience when he told that, after a year passed in writing "dissertations" on philological and philosophical subjects, he underwent nine hours *vivâ voce* examination in one day by eight German professors in as many different subjects! The majority of German students—except in the faculty of medicine—do not take a degree at all, but only pass their "Staatsexamen." It is the custom in Germany for a student to have been to several Universities before settling down at one for examination purposes—a system which the lecturer thought a very good one, on account of the facility it affords the student for becoming acquainted with the leading men in his subject.—*Science*, January 17, 1890.

Intestinal Concretions.

At a recent meeting of the Pathological Society of London, reported in the *Medical Press and Circular*, Feb. 12, 1890, Dr. Delepine read a paper on intestinal concretions, in which several cases of the affection were described, and the chemical structure of the enteroliths explained, these bodies being shown to consist of calcium salts aggregated round vegetable *débris* from ingested food. The retention of such substances through constipation or obstruction of the bowel afforded the opportunity for the deposit of the coating material upon them, and one case of an interesting nature was quoted, in which recto-vesical fistula was diagnosed from the presence of the outer coat of barley grains in the urine. In another instance, large quantities or concretions, due to olive oil taken for solution of gall-stones were found in the feces, and on examination proved to be made up of crystallized fats.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

ADVANCE IN MEDICAL EDUCATION IN AMERICA.

A careful comparison of the Sixth Report of the Illinois State Board of Health on Medical Education, with the report for 1889, shows that there has been greater progress in the direction of a higher medical education during the period which has elapsed between these last two reports, than for any similar period in the history of the country; indeed, the progress has been greater than for half a decade. This is indicated by the increase of courses for instruction, like those instituted by the Johns Hopkins and Clark Universities, and by the fact that the number of colleges which require a graded course of lectures for three years, has increased twenty-five per cent.

Perhaps the most healthful sign that the people are awakening to the need of educated physicians is found in the passage of an act, in the State of New York, requiring a preliminary examination of students about to enter upon the study of medicine, by the Board of Regents of the University of that State. An attempt to repeal this law has been resisted by a popular outcry, which is the best possible evidence that an overwhelming public sentiment is behind the law. There has been an increase of six per cent. in the number of colleges requiring preliminary examinations, which is further proof that a popular sentiment exists favorable to raising the standard of general education for medical students, and the passage of medical practice acts by Florida, Tennessee and Oregon are evidences in the same direction.

Summarizing and comparing the tables in the Report, it will be seen that there are 139 colleges in existence, against 129 in 1886, and 131 in 1889: of these there are 126 in the United States and 13 in Canada at the present time. In the present report there are 149 institutions that are extinct, including 18 that were fraudulent.

In 1880 the number of colleges exacting certain educational requirements for matriculation was 45 (the Report we are quoting from says "1882" and "145," but these figures are typographical errors); in 1886, 114; in 1889, 117; in the present report, 124.

In 1882 the number of colleges requiring attendance on three or more courses of lectures was 22; in 1886, 41; in 1889, 47; in the present report, 64. In 1882, 42 colleges had chairs of hygiene, and 61 had chairs of medical jurisprudence; in 1886, 110 had chairs of hygiene, and the same number had chairs of medical jurisprudence; in 1889, 117 taught hygiene, and 112 medical jurisprudence; in 1890, 119 teach hygiene, and 114 medical jurisprudence.

The average duration of lecture terms in 1882 was 23.5 weeks; this rate gradually increased until in the present report it is 25.5 weeks, or an increase of two weeks.

The number of schools having terms of five months and more in the year 1882, was

101; in that of the present report is 121. The number having six months or more in 1882 was 42; in that of the present report (1889–90) it is 76.

There are now in the United States 22 licensing and examining bodies that do not give instruction. It is a matter of importance that the work of these examining boards should be as uniform as possible, in order to bring about the best results so far as medical education and the regulation of the practice of medicine are concerned. The difficulties incident to divided and limited jurisdictions would thus be overcome, and the work made broader and more national in its character. Unless this is done, owing to frequent changes of residence by medical men, repeated examinations become onerous, and in some cases work hardship. This is one of many good reasons for trying to secure cooperation and uniformity of action in issuing and recognizing certificates of examination by the various boards.

If this course is adopted, it will furnish facilities for the investigation of the character of applicants when removing to other States, as experience has taught that graduates having diplomas from some of the best medical colleges, or those who have passed a good examination, are frequently the greatest professional frauds and scoundrels. Knowledge of the history of these men, thus obtained, would assist in preventing their being licensed in other States, and would exercise a supervision over all which would do much towards upholding the *morale* of the profession.

There has been an increase since the last report of one college for women, there now being seven in the United States and two in Canada. The number of colleges for both sexes has increased by nine.

The total number of graduates in the United States in 1881–82 was 4,555; in the present report for sessions 1888–89 it was 4,337. The percentage of graduates to matriculates for the former period was 36.3; for the year 1888–89 it was 31.6.

The report gives a list containing names of 27 colleges which require three courses of lectures and a year of study with a preceptor, while in the report for 1889 there were only four. It is altogether probable that Harvard University Medical School, the College of Physicians and Surgeons in New York City, University of Pennsylvania, Johns Hopkins University, University of Michigan, Chicago Medical College and St. Louis Medical College, will in a short time require four annual courses of lectures. There are twenty-two colleges which require, or will require three annual courses of lectures, as compared with thirteen announced in the report for 1889, of which two, the Kansas City Homœopathic Medical College and the Physio-Medical College of Indiana receded from their announcements.

The present indications are that three-fourths of the Medical Colleges of the United States will, within the coming year, voluntarily adopt the regulation of this Board, made July, 1887, requiring that after sessions of 1890–91, graduates shall have had four years of study and attended three annual courses of lectures. The remainder will be compelled to fall into line, or cease their existence.

The above is from Dr. Rauch's Report to the Illinois State Board of Health; and we quote it, not only as justifying the hopes and expectations which have often been expressed in the REPORTER, but as furnishing evidence of the debt of gratitude which the medical profession in the United States owes to this admirable and indefatigable laborer in the cause of reform.

SEWER CONSTRUCTION AT RANGOON.

We learn from an interesting paper in the *Engineering and Building Record*, March 15, 1890, that a new system of sewerage has been put in operation in Rangoon, the capital of British Burmah. Rangoon is a city having a population of 100,000 persons, and is a flat and low-lying city on the bank of

the Rangoon River, which in spring tides and floods rises to the level of many of the streets. Under such conditions the construction of large sewers through the loose silt and water-logged ground, with the building and operating of a pumping station to discharge the sewage into the Rangoon River, would have cost so much that a cheaper solution of the problem was sought in the Shone system. The work was designed and carried out by Shone & Ault, civil engineers, of London, in a manner described and illustrated in the paper referred to. The city is divided into twenty-two sections or districts. In each district the houses are connected with iron gravitation pipes six inches in diameter, which in turn are connected with a hydro-pneumatic ejector station, from which the sewage is forced into an iron sewage main and thence into the river near the town and at a level three feet below that of the lowest tide.

The power that expels the sewage from the ejectors is compressed air, which is produced at an air-compressing station, and is supplied to each ejector by a small cast-iron pipe connected with the automatic valve fixed on the top of the ejector. The sewage gravitates from the sewers through an inlet pipe into the ejector and gradually rises therein, until it reaches the under side of a bell at the top. The air at atmospheric pressure inside this bell is then inclosed, and the sewage continuing to rise outside and above the rim of the bell compresses the inclosed air sufficiently to lift the bell, spindle, etc., which opens the compressed air admission valve. The compressed air thus automatically admitted into the ejector presses on the surface of the sewage, driving the whole of the contents before it through a bell-mouthed opening at the bottom, and through an outlet pipe into the iron sewage rising main or high-level gravitating sewer, as the case may be. The sewage can escape from the ejector only by the outlet pipe; the instant the air pressure is admitted on to the surface of the fluid the valve in the inlet pipe falls on its seat and prevents the fluid from escaping in that direction. The fluid passes out of the ejector until its level falls to a cup at the bottom of the ejector, and still continuing to lower, leaves the cup full until the weight of the liquid in the portion of cup thus exposed and unsupported by the surrounding liquid is sufficient to pull down the bell and spindle, thereby reversing the compressed air admission valve, which first cuts off the supply of compressed air to the ejector and then allows the air within the ejector to exhaust down to atmospheric pressure. The outlet valve then falls on its seat, retaining the liquid in the sewage rising main, and the sewage flows into the ejector through the inlet again, driving the free air before it through the air valve as the sewage rises, and so the action goes on as long as there is sewage to flow and compressed air is supplied.

This ingenious system includes, it will be seen, the use of the river as a place of deposit for the sewage. This is an objection to any modern sewerage system, and one which we trust will some day be done away with forever. But the system for Rangoon has the advantage that it could be adapted to any method for the utilization of sewage which might commend itself to the judgment of the government hereafter. It provides a system by which the sewage can be conveyed, in sealed pipes, from the various points of connection to the point of final discharge; and that point could be as easily a station for burning or utilizing the solid residue, as the river.

The system as described in the paper from which our facts have been taken, is well worth the study of sanitary engineers and of physicians interested in the study of sanitary questions.

ENTRANCE OF AIR INTO VEINS.

The *Bulletin Médical*, April 2, 1890, contains a report of a communication recently made by M. Cassaet to the Society of Anatomy and Physiology of Bordeaux, bearing upon the very important question of the re-

sults of the fact of entrance of air into the veins. It seems that M. Cassaet was doing a tracheotomy, without anæsthesia, upon a young man twenty-nine years old, with tuberculosis and stenosis of the larynx, who was suffocating. In the operation M. Cassaet cut a superficial large vein in the neck, which he had distinctly seen in the line of the incision a short time before. The opening of the vein was accompanied by a very distinct whistling sound, which seemed to indicate that air had been admitted to it. The vein was immediately caught and tied, and the operation was suspended. The patient gave no immediate evidence of having suffered any harm by the accident. On auscultating the heart, M. Cassaet discovered the following interesting points: Over an area covering about ten centimeters, the centre of which corresponded to the region of the tricuspid valve, there was heard a very distinct bubbling noise, of a metallic character, which was synchronous with the systole of the heart. This region seemed to extend, and at the same time the bubbles seemed to become gradually more numerous and larger. After a time the noise became more and more limited to the region of the tricuspid valve, and the bubbles diminished in volume, somewhat in the manner of the noise of a large râle, which by successive stages is converted into a subcrepitant râle. The bubbling sound disappeared after twenty-five minutes. In spite of the presence of this enormous quantity of air in the heart there was no serious disturbance of the pulse or respiration. The dyspnœa which had existed before the accident did not become any more intense. The pulse became gradually soft and compressible, but this improved as the bubbling sound disappeared. After a lapse of twenty-five minutes the patient for the first time presented some symptoms of asphyxia—cynanosis, chills, perspiration, and apnœa, which, however, ceased immediately upon the application of electricity.

The operation of tracheotomy was then resumed and completed. Some hours later the patient desired to be raised up upon a chair, and the attendant had hardly done this when he suddenly died.

At the autopsy, in addition to the lesions of tuberculosis in the larynx, the trachea and the lungs, the heart was found to be distended by a clot, and the arteries and veins with black blood, which did not contain any bubbles of air. The divided vein was discovered at the level of the lower end of the incision.

It appears from this account that the patient inspired a quantity of air into his heart and that this did no immediate harm, although after a short time—twenty-five minutes—there were manifestations of depression and suppressed aëration of the blood, which may have been due to the passage of the bubbles into the lungs, and their very general dispersion through them. It is possible also that in this way the blood became freed from the air, although it is hard to understand how this could have made the circuit of the circulation without producing any manifestations until it arrived in a very finely divided condition—as it must have done—in the lungs; and that there, when so finely divided, it should have produced cynanosis. In fact it is very hard, without very careful reflection, to draw any precise conclusions from the report of this case. None the less it is an extremely interesting one, and deserves to be placed on record as a contribution to the study of the subject of the entrance of air into the veins. Those who are familiar with the records of the subject, and who have had some experience in analyzing reports of cases in which it is supposed that air has found entrance to the veins of man, may be able to eliminate from this account the elements of error or uncertainty in its details, and to deduce from its more certain points some useful lessons of theory or practice in regard to a subject which has lately attracted considerable attention, and which is at all times one of great importance.

THE CURSE OF STREET MUSICIANS.

The Medical Profession has an immediate interest in everything which concerns the health and comfort of the community, and is sensitive to many sources of injury to health which sometimes seem rather trivial to those less familiar with sickness. One such source of injury is the distress and nerve strain caused by street noises. There are in every city thousands of persons, day and night, who lie on beds of suffering, of weakness, or of weariness, longing for sleep, and finding its approaches scared away by sounds from the streets. Some of these sounds are unfortunately unavoidable. But the more of these there are, the more is it important that those which may be prevented should be removed from the list of afflictions of city life.

Just now we invite the attention of the readers of the MEDICAL AND SURGICAL REPORTER to the injury inflicted by strolling musicians in all cities. Of late years these have multiplied to such an extent that scarcely any season of the year, or any time of day, or any part of a large town is wholly free from the blaring strains of brass instruments or the horrible confusion of the modern hand-organ.

The experience of every physician must have furnished him with illustrations of the damage these noises do to the sick: the children waked from the sleep which their poor little frames needed; the old people, robbed of their short respites from wakefulness; the brain-weary, cheated of their release from care and thought; the nervous, irritated and exasperated almost to madness—in fact, every physician must look upon strolling musicians as a source of most serious injury to health as well as to comfort. For this reason the physicians of Philadelphia will be glad to know that an attempt is being made to curtail the extent of the harm done by them in this city. An ordinance will be considered in the City Councils next week, which gives to householders the right to require any street musician to "move on," if disturbing him or his family, and we hope it will pass. We have only one thing to suggest in regard to it, and that is that it might be amended so as to give to every person whatsoever the right to require street musicians to depart, and not to householders only.

Those of the readers of the REPORTER as have opportunity will do their fellow-man a service if they will use their influence to have them delivered from the source of distress and suffering which is to many a veritable curse.

STATISTICS OF PASTEUR'S TREATMENT OF HYDROPHOBIA.

The *Journal de Médecine*, March 30, 1890, contains a list of persons who have died after receiving the so-called "preventive treatment" at the hands of Pasteur and his assistants in Paris, giving in each instance the name of the individual and other details. The whole list includes ninety cases. The editor, referring to it, calls attention to the great contrast between the claims of Pasteur and his followers that the method is a humane and useful one, and the fact that since it has been practiced there has been an actual increase in the number of deaths from hydrophobia in France; and he might have made the case appear much more impressive by adding to the list of deaths the vast number which it is claimed would have succumbed to hydrophobia if they had not been treated by Pasteur. The total is a number which would be incredible to any calm and critical investigator familiar with the history of hydrophobia in France and elsewhere; and it is astonishing to see how unrecognized this fact is in general, and how unreservedly the statistical juggling of Pasteur and his followers is accepted by many medical men.

PARACRESOTINIC ACID. — Paracresotinic acid is the latest addition to the interminable list of antipyretics. From 2 to 3 drachms of the sodium salt have been given within the space of 24 hours.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

MANUAL OF SKIN DISEASES, WITH SPECIAL REFERENCE TO DIAGNOSIS AND TREATMENT, FOR THE USE OF STUDENTS AND GENERAL PRACTITIONERS. By W. A. Hardaway, M. D., Professor of Skin Diseases in the Missouri Medical College and in the St. Louis Post-Graduate School of Medicine. Square 8vo, pp. viii, 434. St. Louis: Theo. F. Lange, 1890. Price, $3.00.

The present book is an outgrowth of Dr. Hardaway's lectures on dermatology. While it has developed into a much larger book than the author had originally planned, he states in the preface that he has endeavored to keep it within moderate compass, and to make it a trustworthy guide, especia ly in diagnosis and treatment. The first part of the book consists of a general introduction to the study of skin diseases, the second of an alphabetical arrangement of diseases for ready reference, and the third of an appendix containing additional formulæ and a diet table.

The style of the author is pleasing; it is terse, direct and clear. We have examined a number of the sections and are glad to say that the directions for treatment are very good, and as a rule not too difficult for a student and general practitioner to comprehend and execute. The author states his own opinions distinctly but modestly, and at the same time does full justice to the opinions of well-known authorities in this department of medicine. We can cordially commend the book to our readers.

THE DISEASES OF CHILDREN, MEDICAL AND SURGICAL. By Henry Ashby, M. D., Lond., Physician to the General Hospital for Sick Children, and G. A. Wright, B. A., M. B., Oxon., Asst. Surgeon to the Manchester Royal Infirmary, and Surgeon to the Children's Hospital. 8vo, pp. xix, 681. London: Longmans, Green & Co., 1889. Price, $6.00.

It gives us great pleasure to recommend this book to the readers of the Reporter. It is a thoroughly good book in both matter and manner, comprehensive, concise, and thoroughly readable. Dr. Ashby has written of the Medical Diseases of Children, and Mr. Wright of the Surgical Diseases of Children. Each has done his work well, and it can be said that the practitioner will find an ample description of almost every diseased condition to which children are subject, together with sound advice concerning its management

The publishers have issued the book in good style. The paper, printing and illustrations are all good. The use of block-letter headlines has added to its usefulness as a work of reference.

New Remedies and Appliances.

In this department, notice will be given of Remedies, Food Articles, and Instruments or Surgical Appliances of which specimens are sent to the Editor; it will bear the same relation to these articles that the department of Book Reviews now does to books.

Fairchild's Pepsin.

Fairchild's pepsin has become so well and widely known that it has little need of special commendation. A specimen just sent us is handsome, and we have little doubt has the strength and purity claimed for it. Years of experience with the preparation of pepsin and pancreatin sent out by Messrs. Fairchild Bros. & Foster have led us to a confidence in them which it is a pleasure to express.

Notes and Comments.

Treatment of Peritonitis.

In a paper read at the recent meeting of the Alabama Medical Association, Dr. W. E. B. Davis, of Birmingham, Ala., said that, from a study of the experiments of Pawlowsky, Grawitz, Wegner and others, he thinks the following points pretty well settled:

First. Simple peritonitis, when caused by a sufficient quantity of a chemical irritant, will produce death by the extent of the inflammation.

Second. Simple inflammation may terminate in septic peritonitis, by producing a weakened condition of the walls of the intestines, which permit the passage of septic germs from the intestinal canal into the peritoneal cavity.

Third. While pathological germs in a small quantity may be absorbed by the healthy peritoneum, without producing a peritonitis, the same quantity combined with a chemical irritant may produce a violent inflammation—the irritant having prevented the absorption of the germs and caused the exudation of a nutrient fluid for their multiplication.

Fourth. Large quantities of septic fluids and microbes always produce suppurative peritonitis; yet, a small quantity of either may be absorbed and destroyed, unless the peritoneum has been weakened by antecedent pathological changes.

Fifth. A septic fluid may gravitate into dependent parts of the peritoneum, and become shut up, either by plastic inflammation, or by a coil of intestine, and thus be prevented from producing diffuse peritonitis, but after a time this may rupture and produce death from general peritonitis.

Sixth. The germs of septic peritonitis will be found in the kidneys and other organs of the body, and in greater quantities, according to the extent and duration of the inflammation.

Seventh. The condition of the peritoneum and the nature and quantity of the

septic product will determine the rapidity of the inflammation, which usually ends in from 48 hours to 6 days, but death may be produced from shock in a few hours. Tubercular inflammation is always slow in its progress.

From a consideration of the foregoing principles, he says the following indications for treatment must be arrived at:

1. Promote absorption of the inflammatory products of simple peritionitis as rapidly as possible, and thus relieve the inflammation and prevent the possibility of septic peritonitis.

2. In the early stage of peritonitis, whether simple or septic, where the cause cannot be determined, hasten the absorption of inflammatory products, etc., with purgatives.

3. When medical treatment fails to give relief, septic fluids should be removed by operative procedure.

4. In localized peritonitis—with circumscribed pus formation—the pus should be removed and the abscess cavity drained.

5. In acute septic peritonitis, operative procedure must be adopted early or there will be no chance of recovery offered by the operation, as the inflammation will become more extensive the longer it continues, and, too, there will be so great a quantity of septic germs absorbed into the system, that death will result from toxemia, even though the local inflammation should be remedied by a late operation.

He quoted from Habershon and others, and states that it has been demonstrated, that in the large majority of cases, that peritonitis is a symptom of some well-recognized lesion of the abdominal or pelvic viscera, and that the only rational treatment must be based upon this conception of the disease. Peritonitis is not a "disease distinct," as taught by Bichat, and upon which teaching the treatment of Alonzo Clark gained such great popularity. The "opium splint" is irrational, for it not only locks up the products of inflammation, but as shown by Wylie, Johnson, Baldy and others, and by his own experience, subjects the patient to one of the greatest dangers of the disease, viz.: obstruction of the bowels from adhesions.

In the case of perforation of the bowel, opium is indicated to relieve pain and shock, and to prevent peristalsis, and further escape of the intestinal contents into the peritoneal cavity. Again, morphine hypodermically may be used, with benefit, in some cases when there is persistent and uncontrollable vomiting; but at the same time, calomel in small and frequently repeated doses, may be dropped on the tongue and the bowels induced to act. There are many cases in which it is absolutely necessary to give a hypodermic injection for pain, but this should never be given in such doses as recommended by the advocates of the opium treatment, and should not be administered at all unless the patient's condition is being made more grave by the shock provoked from pain.

The first two indications for treatment are best met by free purgation, as taught by Tait and others, and the majority of those who have adopted this plan select the magnesium salts, as they produce very large watery stools. When the stomach rejects salts, calomel may be used.

He refers to a large number of cases treated by him in the most satisfactory manner by purgation—and among them several cases of threatened peritonitis, after laparotomies. During the past year he has not waited for symptoms of peritonitis after a laparotomy, but begins the use of small doses of salts, and if not retained, of small doses of calomel, a few hours after the patient gets from under the influence of the anæsthetic, and aids the purgative by the administration of enemas of milk and whiskey every third hour, which relieve thirst, and stimulate and nourish the patient, if retained.

In these cases he has had to give an occasional hypodermic of morphine, but this did not prevent the bowels acting. He has had to depend on calomel oftener than salts, as it was not rejected. He reports cases illustrating how purgative treatment aids in diagnosis, and others to show how all symptoms may be masked by opium, and an operation delayed too long—and concludes by stating that it is very important not to resort to the free use of morphine, unless an operation has already been decided on, and this administered to relieve pain and lessen shock.

Abdominal Surgery in Cuba.

According to Dr. Barrena, the results of abdominal surgery, as practiced by himself and some of the other leading surgeons in Cuba, have hardly been as satisfactory as could be desired. Of 39 cases of ovariotomy, 12 were fatal. Of 11 cases of hysterectomy

no less than 9 were fatal; 3 cases of miomotomy, 3 of salpingotomy, and 1 of ligature of the tubes, were all successful, but 4 cases of exploratory incision proved fatal to 3 of the patients, and the only case of vaginal hysterectomy was also fatal. Altogether, out of 62 persons operated on, no less than 25 died. It is to be hoped that this courageous statement of actual facts may tend to deter surgeons, who might otherwise be induced by the brilliant results of abdominal operations frequently published, from entering with too light a heart upon operations of this nature. The unfavorable results referred to may, perhaps, be partially explained by the insanitary condition of Havana, and probably of other Cuban cities. This subject was also treated during the Congress by Dr. Wilson, who pointed out that the bad water and want of a proper system of sewerage, together, doubtless, with the heat and moisture of the climate, raised the death-rate of Havana to a figure about double that which denotes the death-rate of London.—*Lancet,* April 5, 1890.

Tuberculosis in Cattle.

In the *Allgemeine Medicin Central-Zeitung,* April 16, 1890, there is a communication of Prof. Eggeling to the Farmers' Club in regard to tuberculosis in domestic animals and especially in cattle. Eggeling, in this, discusses particularly the etiological relations of tuberculosis, and says that heredity plays a very small part in this disease in cattle, and he thinks it is more dependent upon infection from breathing in or eating infectious matter. The course of tuberculosis in cattle is a relatively tedious one, so that half a year may pass by before a cow which has been infected by a tuberculous neighbor will show the first signs of the disease. It advances more rapidly in young cattle; and calves which have ingested tuberculous milk succumb very rapidly: probably because their immature organs have less power of resistance to the invasion of the tubercle bacillus. The diagnosis of the disease thus is exceedingly difficult in the early stages, and its cure is by no means easy. Therefore it is desirable that diseased cattle should be destroyed as the only safe means to a thorough cleansing and disinfection of the place. In regard to the possibility of the communication of tuberculosis to human beings by ingestion of the milk of tuberculous animals, Eggeling recommends that only such milk shall be used as has been collected from a large number of animals in a herd, so that by the mingling of healthy milk with that of diseased animals the proportion of infectious matter shall be reduced.

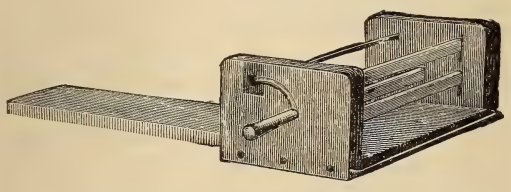
Teeth in Ovarian Cysts.

The subject of minute examination of the teeth found in ovarian dermoid cysts has not, in the opinion of Mr. Bland Sutton, received attention commensurate with its scientific interest. The age at which these teeth develop is uncertain: for instance, cases have occurred where ovarian cysts in children maintain fully formed teeth; whereas in adults they may be found only in a very early stage of development. Nor is there any certainty as to the time of eruption or shedding of these teeth, being in this respect unlike hair, which becomes gray and falls out concomitantly with the hair of the head. The number of teeth in ovarian cysts varies considerably, two to four being common, but it may reach three to four hundred. Owen, Salter, Coleman and Tomes mention ovarian teeth, but give only meagre descriptions of them. Ovarian teeth have enamel and dentine, the enamel being generally irregular, with deep fissures and pits. They may be like normal buccal teeth surrounded by a bony alveolus, and possess an alveolar-dental periosteum, and this resemblance to the upper or lower jaw has given rise to the erroneous idea that dermoid cysts are included fetuses. In shape these teeth may be divided into three groups—multi-cuspidate, bi-cuspidate and canineiform. As a general rule the crown and fang are in inverse proportions as to size, and multiple fangs are very exceptional. The cementum varies considerably; sometimes there is only a thin layer on one side of the fang; in other cases it is absent altogether. Salter described nerves as being distributed to ovarian teeth, but this has not been confirmed. In one especially suggestive case, where two ovarian cysts were present, Mr. Bland Sutton found in one tissue indistinguishable from brain matter, and in the other teeth, in which, however, he was unable to demonstrate satisfactorily the presence of nerves. The microscopical specimens exhibited of developing ovarian teeth showed that the type follows that of normal buccal teeth, there being a papilla and a

dipping down of epithelium to form the enamel organ. The theory that caries ever takes place in ovarian teeth is altogether unsound, and is due to the deceptive appearance of the enamel, which is often of worm-eaten character, the ravines and pits filled with fibrous tissue, which in macerated specimens leaves a cavity much resembling caries; in other cases, moreover, the pulps may absolutely penetrate the enamel. Mr. Charters White supplemented the paper with a description of the irregular arrangement of the enamel and dentine in these teeth as shown under the microscope. — *Lancet*, March 8, 1890.

An Improved Bandage Roller.

For over a year past a new bandage roller, devised by Mr. John Borham, one of the attendants, has been in use at Bellevue Hospital and several other public institutions.



This presents some features which make it preferable to any other bandage roller we are acquainted with.

The apparatus will be readily understood by examining the illustrations. A piece of bandage muslin, of a width somewhat narrower than the inside space of the roller, is passed behind the metallic bar in front of the bottom board, then over the three wooden rectangular bars which at the same time secure the two side frames together, and having been adjusted by its edge to the square steel axle the latter is turned by means of a winch, thus winding the muslin tightly and smoothly upon the axle in any thickness compatible with the distance of the nearest bars. It will, of course, be readily understood that during the passage of the strip of muslin over the several sharp-edged wooden bars, every crease and unevenness is removed from it, so that the final roll produced upon the axle is perfectly homogeneous. The axle itself is slightly tapering from the winch towards the other end, and when the roll has arrived at the proper thickness, and the muslin has been cut, it is simply pulled out. The roll may then be cut with a sharp, flat-bladed knife into bandages of any desired width.—*American Druggist*, April, 1890.

Phthisis Treated with Calomel.

Dr. Dochmann, in the *Deutsche Med. Wochenschrift*, Feb. 13, 1890, recommends calomel in the following formula, in the treatment of incipient phthisis:

℞ Hydrag. chlorid. mitis . . . . . gr. x
Pepsini . . . . . gr. lvi
Tinct. opii . . . . . gtt. xxx
Extr. phellandrii . . . . . q. s.
Fiant pillulæ nos. lx.

The above formula will be found especially useful. The gastric complications are marked. In hemoptesis the opium may be replaced by ergot; and, if the cough is severe, extract of hyoscyamus may be substituted.

Parasitic Fetus.

The *Lancet*, February 22, 1890, says that one of those singular malformations described as "parasitic fetus" has been attracting some attention at Demerara. A coolie was admitted into the Colonial Hospital suffering from a tumor in the right loin. The man died, and at the *post-mortem* examination the tumor proved to be possessed of a cranium, with hair attached, an imperfect nose and mouth, no hands or feet, but the rudiments of male genitals. The subject of this "autosite" was thirty-two years old.

NEWS.

—The Massachusetts State Board of Lunacy and Charities has formally ordered the return to Europe of a leprous Swedish woman, who arrived in Boston on April 28.

—Supervising Surgeon-General Hamilton, of the Marine Hospital Service, reports that the new fumigating steamer is now in service at the United States Quarantine Station at the Delaware Breakwater.

—The annual meeting of the Medical Society of New Jersey will be held in the Heath House, Schooley's Mountain, on Tuesday, June 10, 1890, at 4 P. M., and will continue in session the following day.

—Dr. John H. Douglas, General Grant's physician at the time of his death, is lying ill at the Presbyterian Hospital, New York. He is stricken with paralysis, and, moreover, is understood to be in reduced circumstances.

—Dr. Samuel Rush Haven, of Chicago, died suddenly in Joliet, Illinois, on Monday of paralysis. He went out with the first troops as a brigade surgeon under General Grant. He was a native of New York State, having been born in Sheridan, Chautauqua county, in 1827.

—The latest improvement at the Biological School of the University of Pennsylvania is a tank for water plants which is to have a surface of 1,000 square feet. Special facilities for the cultivation of these plants are rare in the United States and this undertaking of the University is therefore particulary interesting.

—Dr. Jennie McCowen has been re-elected President or the Davenport (Ia.) Academy of Natural Sciences by unanimous vote. Dr. McCowen was one of the earliest women members of the New York Medico-Legal Society. She was last year elected one of the Vice-Presidents of the International Medico-Legal Congress.

—The Chenango County Poorhouse and Insane Asylum, located at Preston, a few miles west of Utica, N. Y., was entirely consumed May 7. There were no provisions for extinguishing the flames. The keepers and neighbors gave their attention to getting out the 125 paupers and insane and let the building burn. These were all rescued, but 11 idiots are missing.

—The Longue Pointe Lunatic Asylum, ten miles from Montreal, Canada, was destroyed by fire May 6, and about 50 of the inmates are believed to have perished in the flames. The asylum was under the charge of the Sisters of Providence, and several of the sisters lost their lives in trying to save the patients. The asylum was founded in 1873, and the amount spent in organizing the institution was $1,132,232, of which the buildings cost $700,000.

—Delegates from the leading Societies and Colleges of Pharmacy in the United States met in convention in Washington, D. C., May 8. The work of the convention is confined to making a general revision of the pharmacopœia and of collection of formulæ used by physicians in their prescriptions. Officers were elected as follows, to serve for ten years: President, Dr. Horatio C. Wood; Vice-Presidents, Drs. W. S. Thompson, D. W. Prentiss, J. M. Flint, A. E. Ebert, and J. W. M. Searcy, of San Francisco; Secretaries, Dr. H. A. Hare and Dr. G. H. C. Klie.

—On May 7 the Memorial Pavilion (children's ward) at St. Luke's Hospital, Bethlehem, Pa., erected to the memory of the son of Mr. and Mrs. E. P. Wilbur, was formally presented to the hospital by them. Dr. Lamberton, President of the Lehigh University, presented the ward to the hospital in the name of the donors, and Dr. William G. Cattell, of Philadelphia, First Vice-President of the Board of Trustees, received the gift for the hospital. The ward is a building of handsome and modern construction, and contains twelve cots and five bedrooms. The ward cost $40,000.

—Over one million dollars is divided among public and charitable institutions of Philadelphia by the late George S. Pepper, according to the terms of his will. Among the endowments most interesting to the profession are the following: University of Pennsylvania, $60,000 for the endowment of a professorship, to be selected by William Pepper, M. D.; Hospital of the University of Pennsylvania, $50,000; Presbyterian Hospital, $50,000; Hospital of the Protestant Episcopal Church, $50,000; Orthopædic Hospital, $25,000; Pennsylvania Hospital, $50,000; Hospital of the Jefferson Medical University, $50,000; Charity Hospital, $25,000; St. Joseph's Hospital, $25,000; Children's Hospital, $25,000; Wills Hospital, $10,000; St. Christopher's Hospital for Children, $25,000; Hospital and Dispensary of St. Clement's Church, $10,000; Children's Hospital, Country Branch, $10,000; Maternity Hospital, $25,000; Northern Dispensary, Southern Dispensary, Philadelphia Dispensary, Howard Dispensary, each $5,000.

CH. MARCHAND'S

Peroxide of Hydrogen,

MEDICINAL (ABSOLUTELY HARMLESS)

H_2O_2

is rapidly growing in favor with the medical profession. It is the most powerful antiseptic known, almost tasteless, and odorless. Can be taken internally or applied externally with perfect safety. Its curative properties are positive, and its strength and purity can always be relied upon. This remedy is not a nostrum.

Experiments of Prof. Pasteur, Dr. Koch, and many other scientific authorities, prove beyond doubt that Germs, Bacteria, or Microbes cause and develop: **NOSE, THROAT, AND LUNG DISEASES—Diphtheria, Croup, Sore Throat, Catarrh of the Nose, Hay Fever, Bronchitis, Laryngitis, Pharyngitis, Whooping Cough, Consumption and other Chronic Affections, specific or not.**

GERMS, BACTERIA, OR MICROBES are instantaneously annihilated when brought into contact with **Ch. Marchand's Peroxide of Hydrogen.** This wonderful bactericide acts both chemically and mechanically upon all excretions and secretions, so as to thoroughly change their character and reactions instantly. By destroying the microbian element this remedy removes the cause of the disease.

CAUTION.—I would earnestly impress upon the profession the very great importance of prescribing only my **Peroxide of Hydrogen (Medicinal)**, from which all hurtful chemicals have been eliminated.

By specifying in your prescriptions "**Ch. Marchand's Peroxide of Hydrogen (Medicinal)**," which is sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing my label and signature, you will never be imposed upon.

Prepared only by

Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

A book containing full explanations concerning the therapeutical applications of **Ch. Marchand's Peroxide of Hydrogen (Medicinal)**, with opinions of the profession, will be mailed to physicians free of charge on application.

¼ lb. bottle, retail, 35 cents; ½ lb. bottle, retail, 50 cents; 1 lb. bottle, retail, 75 cents.

SOLD BY LEADING DRUGGISTS.

Laboratory, 10 West Fourth Street, New York.

BURN BRAE

A PRIVATE HOSPITAL

--FOR--

MENTAL and NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

EXTENSIVE AND BEAUTIFUL GROUNDS, affording perfect privacy and pleasing variety. House and surroundings unusually attractive and cheerful. Heat, light and ventilation perfect.

A PLEASANT, SAFE AND HEALTHFUL HOME,

With constant professional supervision. Music, games, open-air amusements, boating, etc., are provided for patients.

THE OLDEST INSTITUTION OF THE KIND IN THE UNITED STATES.

Both sexes received. A limited number of opium habitues admitted. Pleasant companions for female patients.

LOCATED A FEW MILES WEST OF PHILADELPHIA,

At Primos Station, on the Philadelphia and Media Railroad, from Broad Street Station, Philadelphia, Pa.

DOUBLE DRAINAGE FOR WOUNDS.—EPITHELIOMA OF THE LIP.—OPERATION UNDER COCAINE.—CIRSOID ANEURISM OF THE LEFT TEMPLE.—LIGATION OF RIGHT CAROTID ARTERY.[1]

BY W. W. KEEN, M. D.,

PROFESSOR OF SURGERY IN THE JEFFERSON MEDICAL COLLEGE.

Double Drainage of Wounds.

Gentlemen: I have frequently insisted upon the advisability of double drainage, or, as I call it, the combined tubular and capillary drainage, for wounds; and I have brought here to-day some dressings to show you why I have done so. You will remember the case of cancer of the breast on which I operated a week ago. Here I show you the first dressing and the tubing, which, as is my custom, I renewed at the end of twenty-four hours. Notice how thoroughly saturated the dressing is with the bloody oozing which always follows an extensive wound. How uncomfortable this stiff, harsh dressing would be if retained. For this reason I always re-dress my cases in twenty-four hours, not only to replace the blood-saturated dressing, with its danger of infection, but also to remove the drainage tubing, which is no longer needed. Another reason for removing the tube in twenty-four hours is that if I left it in for a week or more a sinus would result. I left the horse-hair in, however, to carry off the slight serous discharge of the next three or four days, and removed it with the second dressing, which I here show you. Notice how slightly it is stained with serum. At the second dressing I removed the horse-hairs, one or two at a time, so as to disturb

[1] Delivered at the Jefferson Medical College Hospital.

the nearly healed wound as little as possible, and I also removed the alternate stitches. The last dressing and final removal of the stitches will be done to-morrow. No better argument than these dressings, and the resulting early healing without any drainage sinus, could be presented as a reason for the more frequent change of dressing than many surgeons still make.

The shoulder case I operated upon four days ago I dress before you now for the second time. Here is the first dressing, which is quite bloody. The second dressing you now see shows but little oozing, only serous in nature. I shall remove the horse-hair to-day, cutting it close at one end so as not to injure the partly healed surfaces by drawing the rough and matted ends through the wound, producing pain and, at the same time, separating the slightly united surfaces. All this minute attention to details contributes to that absolute rest which is needed to secure early and complete healing. I will now remove the alternate stitches, and at the next dressing three or four days later I will remove all of the remaining sutures. Here is her temperature chart, and 99.6° is the highest record. It is a normal operation chart.

Epithelioma of the Lip.

The next case I have to show you is one of epithelioma of the lower lip. The patient is a man, 53 years old. We never see this disease in a young man. Six years ago, he first noticed a little eruption upon his lip which slowly increased in size. Six months later this was cauterized and its growth in this way retarded for two years. For the past three years and a half, however, it has been slowly growing until it has reached its present size, which is about that of my thumb-nail. His physician told him it was due to the smoking of his pipe. This would be very possibly, but not certainly, the case. One thing is certain clinically, that this form of disease is, curiously, limited almost entirely to the lower lip, and is far more frequent in men than in women. It is the least noxious and fatal of all the forms of cancer. There is but one cure for it, and that not always a cure: namely, early excision of a V-shaped piece of the lip including the growth, and the drawing together of the edges. The only point especially to be borne in mind is that whatever means of approximation are used, it must go down to the mucous membrane, or the coronary arteries will give rise to a serious and even dangerous hemorrhage.

There is another point in connection with an epithelioma of the lip which is worthy of remembrance. If you are called to see a patient, especially if it be an old man, with an abdominal growth, or a tumor in any other portion of the body, and notice an old scar upon his lip, especially upon the under lip, examine such a growth with care, for you have good reason to believe that it may be a cancer.

Operation under Cocaine.

In this case I will not etherize the patient, but will try an injection of a 4 per cent. solution of cocaine. This has been injected around the growth ten minutes ago, and I shall now take out a small V-shaped piece of the lip. I shall put a large pair of spring forceps on either side of the lip which will control the hemorrhage to a large extent. On removing the V-shaped piece you will observe that the arteries are very nicely controlled by the forceps. In inserting the pins, I always take first the one next to the free border of the lip so as to control the hemorrhage and get an accurate approximation of the mucous surfaces so as to make the lip as sightly as possible. Three pins are inserted, and with two or three turns of the ligature the bleeding is entirely under control. After taking off the free points of the pins I apply a simple dressing. The patient tells me he has experienced no pain whatever. Corning has suggested that a round rubber pessary, or other similar means, may be used to keep the cocaine in the tissues, this is in many cases a very useful hint.

Cirsoid Aneurism of the Left Temple.

The next case is an exceedingly serious one, and one in which there has been a good deal of surgical interference already. The history of the case is as follows: The young man is twenty-two years of age. Twenty-one months ago, while playing ball, he was struck by the ball upon the left temple, and knocked down. He remained dazed for fifteen or twenty minutes. On rising he noticed a small swelling of the size and shape of a peanut. This is quite different from the ordinary swelling arising from a blow, which is more diffused and globular, and points probably to a very localized lesion, probably of the temporal artery or one of its branches. This swelling was hard and painful on pressure. Five months afterwards, while throwing a

ball, he felt something give way here, and there has been a heavy pulsation ever since. On August 29, 1888, and again upon November 6, 1888, he was operated on by Dr. Barton, who ligated the left common carotid, and pinned the small branches supplying the swelling at the first operation. This did not prove successful. He then surrounded the growth entirely with large pins and a double row of ligatures. This controlled the circulation, and was followed by an apparent cure for some months. The growth then returned, and he injected alcohol around the swelling to produce a coagulation of the blood. Ten to twelve hypodermics were given every other day, and this again appeared to result in a cure. It has, however, again returned, and the young man is now more than ever in serious need of assistance.

This is a cirsoid aneurism, that is, an aneurism like a varix. An aneurismal varix is a single vessel which has become tortuous and dilated. The cirsoid aneurism covers in the whole of the temple, the side of the cheek in front of the ear, and lower part of the scalp. There is great dilatation and elongation of all of the vessels here, not of the veins so much as of the arteries; and more than this, at three places there are localized dilatations or really aneurisms of the vessels. The seat of such conditions is usually upon exposed sites, such as the head and the hand, and not seldom in the orbit. The cause here is clearly an injury; but they may occurr congenitally as seen in a modified and much less serious form in cases of ordinary nævus.

On this man's head is a large mass rising to from one to one and a half inches above the normal level of the scalp. It is sacculated in appearance and soft to the touch. I am able to squeeze all of the blood out of it. If I put my ear to it, either directly or through a stethoscope, I can hear a distinct aneurismal bruit; if I compress it lightly I can get an aneurismal thrill. If I squeeze out all of the blood from the sac and then apply pressure at its upper part, on the deep temporal arteries, the sac slowly fills again as the blood leaks in through other vessels, but if no such pressure is applied it instantly refills, thus showing that its chief supply is by the deep anastomoses. The occipital artery, which was pinned by Dr. Barton, is again pulsating. In the right carotid there is very marked pulsation, showing that it also is dilated, while the left carotid, which was tied eighteen months ago, has become pervious above the ligature, and is beating forcibly. Dr. Barton also ligated the left internal jugular vein. The external jugular vein of the left side is now dilated, as are also the superior thyroid vein and artery of the same side. The walls of this sac are thin, and if left alone it will eventually give way, and the man will die of a sudden hemorrhage. The diagnosis here is easy. The trouble all lies in the treatment. In the *International Encyclopædia of Surgery*, Wyeth has given in tabular form the results of the treatment pursued in such cases. In seventy-three cases the common carotid was tied, and of these twenty-one died, and of the fifty-one who recovered only twenty-seven were cured—a little over one-third. Both carotids were tied in nine cases, with two deaths. So in this direction we have not a very promising outlook. Excision can be tried, and in certain cases, where the tumor is not too large or deep, is the best plan. But here I think you will agree with me that to try excision would simply result in a fatal hemorrhage. Not only is the tumor supplied by the superficial vessels, but by the deep also, and from both sides. Another method, that of Barwell, of carrying a continuous deep buried suture all around the growth, and then drawing upon it like the string of a purse, is also not applicable, for it could not be made to include the deep-lying vessels. Nor is direct compression applicable here, and even were it safe to try this method, it must be done with great care, as it may produce an ulceration which would but hasten the fatal result. Injection of the perchloride of iron is an excellent method, and Dr. Barton employed an analogous one, the injection of alcohol, with good results. To-day I shall probably employ a combination of these methods.

I desire first to secure the peripheral vessels by means of a sharply-curved needle, tying the ends over an elastic rubber tubing. Then I shall tie the right carotid artery. This will be a matter of some difficulty, especially since the superficial veins are of considerable size and probably the internal jugular is large. The true line of safety always in tying the carotid, is to open its sheath away from the jugular vein, that is, towards the middle line. The line of the artery is under the anterior border of the sterno-cleido-mastoid muscle. I shall tie the artery in the triangle of election above the omohyoid muscle. I shall tie the common trunk, and

not the external only, so as to control the deep as well as the superficial anastomoses. This will be at not a little risk to the patient's brain, and may result in softening there, a risk that is much lessened by the dilated state of all the vessels. Then, or later, I may go on to the left side where the artery has become pervious through the anastomosis of the two superior thyroids and possibly of other vessels, and tie the artery there again at a higher level than before. Finally, I may inject some of the tincture of the chloride of iron into the tissues. Each step will be decided at the time. I now divide the skin and superficial fascia with the platysma myoides, thus reaching the sterno-cleido muscle. The incision is three inches long and the middle of it is opposite the circoid cartilage. Under the anterior border of this muscle I shall find the artery. Upon the outer side of the artery is the vein, and between the artery and the vein and behind them is the vagus nerve. I shall open the sheath of the artery well towards the middle line so as to avoid any injury to the vein, carefully loosen the artery, pass the ligature around it and secure it. The first thing to do is to find the superficial vessels and tie them but I am utterly unable to detect them, and I must, therefore, let them go until a day or two later, when, should I then find them, I will probably inject a little cocaine and pass a ligature under them. The size of the superior thyroid and external jugular veins is nothing to-day compared to what it was yesterday. I shall proceed now to tie the right carotid. I have now retracted the inner border of the sterno-cleido and I see the descendens noni nerve. I have now found the omo-hyoid muscle, and just above it I will tie the vessel. In the groove between the artery and vein is something which looks like the pneumogastric nerve. This might lie between and behind the vessels. Whether it really is the nerve or not I do not know. If it be it is a most unusual anomaly. I have now easily found the artery, and shall pass my aneurism needle, armed with silk, under it, and tie it, cutting the ends of the ligature off short, so as to get primary union. The rule is to pass the ligature first between the artery and its most dangerous neighbor the vein where you can see it and carefully guide the point of the aneurism needle. To reverse this method is to run the risk of puncturing the vein by the unseen point of the instrument. It is not uncommon to have a convulsion follow the ligation of the carotid by cutting off the blood supply to the brain. There is none following this, however, though there is a pallor of the face and scalp. I insert a small piece of drainage-tube here. Now on compression over the tumor I can feel only a slight thrill. His color is not very good, and as most of the access of the blood is arrested, I shall simply ligate a sub-cutaneous vessel here, and do nothing more to-day on account of his condition. In two or three days I will perform the other operation I have suggested.

SUBACUTE PERITONITIS. — PLEURISY WITH EFFUSION.[1]

BY ARTHUR V. MEIGS, M. D.,

VISITING PHYSICIAN TO THE PENNSYLVANIA HOSPITAL, ETC.

Subacute Peritonitis—Medication or Operation.

Gentlemen : I found this man in the hospital, yesterday, when I reached here. He was in my charge some years ago. He is thirty-eight years old. He says that he was in the hospital in March last with the same trouble that he now has ; but he seems to forget that in the summer of 1887 he was also here under my charge. His present sickness began two years ago with an attack of peritonitis. Since then he has always had pain in his abdomen, more or less severe in character. At that time his peritonitis was supposed to be tubercular in nature. On admission his bowels were regular ; he had pain in his left side over the sigmoid flexure ; the examination of his lungs and heart was negative ; his urine was acid in reaction, of a specific gravity of 1.026, and of a pale amber color. This was upon the fourteenth of November last. From this date the notes of the case run on without giving us any facts of special interest. On the twenty-sixth of November his abdomen was distended and tympanitic. On the twenty-third of January he got out of bed, and has been doing well since. This last attack, then, lasted about six weeks, during which time he was ill with pain and tympanites. Since then he has been better. His temperature sheet shows us no fever record. This is

[1] Delivered at the Pennsylvania Hospital.

a circumstance which is often noted in acute peritonitis, and is an important point to remember. His temperature was never above $99\frac{2}{5}°$, except once, on January 3, when his physician, Dr. Longstreth, tells me this was due to an attack of influenza. We must remember, then, that it is possible to have an acute inflammation with no fever.

The man came into this house first in the summer of 1887, and was in a long time, suffering with a prolonged attack of subacute peritonitis, severe and obstinate, and accompanied with a tympanitic swelling of his abdomen, great pain, and obstinate constipation. In the summer of 1888 I saw the man acting as a coachman at a neighboring summer resort; and there he told me that he was experiencing some slight pain at that time. From this time he dates his trouble, and since then he has been under the weather with pain in his belly.

As I proceed now to make a physical examination of his present condition, I find nothing peculiar in his belly, except that it is rather full and tympanitic. He is a muscular man, but is not obese. On palpation, his belly feels a little harder to my sense of touch, but very slightly so; in technical terms there is here a slight degree of doughy induration. In an acute condition of an attack of peritonits you cannot touch a patient as I am doing here. This man has no pain. Palpation, then, reveals no tumor, nor any localized hardness of any kind, but only this slight degree of induration. Percussion reveals a moderate amount of tympany, but nothing which can be strictly called unnatural. I will now see if there is any enlargement or diminution in the size of the liver. Percussing in the nipple line, I find the liver to be normal as regards size. There is a slightly increased area of dulness in the splenic region. This does not indicate anything, however; for, if the colon should happen to be full of feces in this situation, we would have this same increase in the area of dulness.

The treatment I employed two years ago in this man's case was that which I am in the habit of using in cases not requiring operation. In the first place, the patient must be put in bed; but it is not as rigidly necessary to keep him flat upon the back in an ordinary case of peritonitis as it is in a case of typhoid fever. It is best not to give patients orders which they will not obey. Still, as a rule, if you can control the patient, keep him in bed. In the second place give him an absolutely liquid diet; small quantities at short intervals. Milk is the best substance to use; but this may be varied as required. Use stimulants if necessary to do so; but as an ordinary thing the patients do not require stimulation. Four ounces of milk every two hours is about the quantity of food which should be given.

As far as medication is concerned, one-quarter of a grain of powdered opium and one-twelfth of a grain of the extract of belladonna, every two hours, is what I give in these cases. At present a regular revolution is going on as regards the treatment of peritonitis. One man says: "Give opium;" and another says: "Give only purgatives, or you will kill your patient." My belief, however, is a middle one. If the case is a medical case and you do not need the advice of the surgeon, or his knife, I give the opium as I have suggested. This will not stupefy an ordinary patient in any degree, as it is claimed that it will do. It simply soothes the pain but will not stupefy the patient one iota. This I regard as the best treatment in such cases.

This plan of procedure cured the patient two years ago, and he returned to his work; but for the past year and a half he has been disabled. The aspect of affairs now is different from what it was then. For a year and a half some irritation has been going on in this belly. Here is a case where we should have the surgeon in, and secure his opinion as to what is going on. Here is a man who certainly has some irritative cause here. If he had had a tuberculous condition here, or a cancerous condition—but he is too young for that—two years ago, he would be dead by this time. There is probably here some other cause for the irritation. The risk is very slight in laparotomy; I think it is estimated at only one-half of one per cent. If this trouble goes on, it is very likely that it will kill the man. Some day, unless attended to, this patient will develop a purulent peritonitis and die. He may have a purulent peritonitis even now. I have seen a patient presenting no more symptoms than he does now, with a purulent peritonitis. The surgeon, therefore, should be called in. If there be found some trouble which can be removed, you have achieved one of the greatest triumphs in modern medicine. I should recommend, therefore, that the operation be performed, and that at once, for it can now be done with the greatest degree of safety.

Pleurisy with Effusion.

This patient is an Italian, twenty-six years of age. He says he has always been healthy. About four weeks ago he had an attack of influenza, lasting for ten days. He then returned to work, but was compelled to stop at once on account of severe pain in his chest. He had a chill and fever, followed in a few days by a cough and expectoration. He was admitted to the hospital on the second day of February, at which time he was suffering with great dyspnœa and pain. His temperature on the evening of admission was 101°, on the next morning 100°; and it has varied between 99⅖° and 100° and a fraction ever since. He has, therefore, had a moderate fever. Thinking himself well of his influenza, but not being well, he resumed his work only to be laid up again. He had been sick for two weeks before his admission into the hospital. I shall now proceed to examine him before you.

Inspection posteriorly shows no difference as regards the size of his chest. I cannot say positively from mere inspection which side is affected, but I should say that the interspaces bulge more upon the left side. There is no difference to be noted in the way the man breathes. In the same way expansion, as shown by palpation, seems better upon the right side. Percussion reveals a dulness upon the left side, which is not to be found upon the right side. At the left apex posteriorly there is a high-pitched tympanitic note; the percussion note at the right apex is normal. There is dulness in the left middle region posteriorly, as compared with the right. At the left base there is actual flatness, extending up to about the middle scapular region. The right base is normal. Anteriorly, the percussion note at the right apex is full, clear and natural; at the left apex it is high-pitched, short and tympanitic. Auscultation shows a good, clear, natural sound at the right apex posteriorly. At the left apex the sounds are somewhat restricted, and tend to be bronchial. In the right middle region the sounds are good, and vesicular expansion is good; in the left middle region there is no vesicular expansion, and only slightly tubular sounds. At the right base the sounds are natural; at the left base there are slightly distant, transmitted tubular sounds, otherwise absent respiratory sounds. Vocal resonance is much louder on the right than upon the left side, except a little above the middle portion of the left side, when it is quite loud. Vocal fremitus is good on the right side, weak on the left side and almost absent at the left base.

This is the condition found at the end of five days in the hospital. The interspaces are fuller upon the left side; expansion is feeble on the left side. Over the lower half of the left lung there is dulness of percussion, and almost entire absence of respiratory sounds. Vocal resonance is less upon the left than upon the right side, except at the root of the lung, where it is loud. Vocal fremitus is weaker upon the left side, and at the base is almost absent. What, then, is the condition here?

This can only be a pleurisy with effusion or a pneumonia. Of course, we have here a pleurisy. There is here a lessening of both vocal fremitus and resonance, while these are both increased in pneumonia. Then, there is an absence of respiratory sound, which is not the case in pneumonia. These signs, together with the bulging of the interspaces, all indicate the existence of a pleurisy with effusion and not of a pneumonia. It is a typical picture of a pleurisy with effusion to a moderate degree. Pathologically, however, we rarely see a pleurisy with effusion without some slight degree of inflammation existing in the bronchial tree or in the lung itself. This man coughs and expectorates, so he has some slight bronchial trouble in addition, which is of no consequence, however.

Now as to treatment. The man was given Epsom salts on his admission, to move his bowels. Time is wanted in the treatment of these cases. Rest in bed, light diet—not absolutely liquid, however—and some tonic treatment, such as Basham's mixture, is all that is needed. There is no fever which requires treatment. If we give him time and rest in bed, he will probably soon recover. The prognosis, then, is good. Almost all cases of pleurisy with effusion recover promptly.

—Sulphur, always heretofore considered an elemental substance, is now declared to be a compound of carbon with other elements. Dr. Theodore Gross, of Berlin, read a paper before the Vienna Academy of Sciences, detailing experiments which seemed to prove that sulphur, especially precipitated sulphur and that in what is known as the allotropic form, is readily decomposed and leaves a residue of carbon.

COMMUNICATIONS.

GONORRHŒAL SALPINGITIS IN ITS SURGICAL ASPECTS.[1]

BY CHARLES P. NOBLE, M. D.,
PHILADELPHIA.

The relation between gonorrhœa and pelvic inflammations in women is a subject which has justly excited much discussion within the past few years. Until Nœggerath proclaimed his views as to the importance of this disease as a cause of pelvic peritonitis, gonorrhœa in women was considered a trivial disorder. Since that time important changes in professional opinion have taken place. Indeed there has been a tendency to attribute all catarrhs of the genital tract, not plainly due to infection during the puerperium, to gonorrhœal infection. In this way I feel sure that injustice has been done to many virtuous women, who have been so unfortunate as to suffer from vaginitis, endometritis or salpingitis. It is not my purpose to enter into a discussion of the conflicting views concerning the importance of gonorrhœa as a cause of salpingitis, but it can be asserted safely that it is a frequent cause of this disease. Hence gonorrhœa in women must be considered as possessing infinite potentialities for harm. The course of gonorrhœa of the Fallopian tube may vary greatly in different cases. The more usual pathological conditions I shall illustrate by the specimens exhibited. But while the course of the disease presents great variations, there are certain peculiarities which it is worth while to recall. Gonorrhœal inflammation is almost invariably a disease of mucous or of serous surfaces. Exceptionally distinctive suppuration, more especially in the ovary, is produced by it. Owing to this peculiarity, fluid accumulations form in the tubes; the fimbriated ends of the tubes become occluded by adhesive peritonitis induced by the infecting agent, and, the formation of pus or of watery fluid by the mucous lining of the tubes continuing, a pyosalpinx or a hydrosalpinx results.

The fact that destructive suppuration seldom results from gonorrhœal inflammation accounts for the essentially chronic course of the disease. It lasts for months and years, sapping the patient's vitality, always producing pelvic discomfort and at times agonizing suffering, and it finally induces a condition of chronic invalidism or renders the sufferer a bedridden wreck. Irregular exacerbations of the inflammatory processes increase the patient's sufferings, or confine her to bed for days or weeks. These acute attacks of pelvic inflammation usually follow menstrual congestion or over exertion.

The extent of the peritonitis which accompanies salpingitis varies greatly. This is a very interesting question. It is considered, and I think rightly, that peritonitis is set up primarily by leakage of gonorrhœal poison through the fimbriated opening of the tube, and that the recurring attacks are due to leakage of the tubal contents through slight ruptures in the adventitious material formed about the end of the tubes. It is possible that the infection may spread through the wall of the tube itself. After slight attacks of peritonitis, nothing may be found, besides the diseased tubes, except delicate, net-like, pelvic adhesions. On the other hand, the most extensive structural changes may be found, usually after many recurring attacks of peritonitis. All the pelvic viscera may be matted together, with or without intra-peritoneal abscesses, or abscesses of the ovaries.

A most important characteristic of gonorrhœal peritonitis is its tendency to localize itself. Exceptionally acute gonorrhœal inflammation will spread through the uterus and tubes and cause acute general suppurative peritonitis and death. This may also result from the rupture of pus sacs in the tubes, the ovaries or the peritoneum. In this respect gonorrhœal peritonitis differs radically from that induced by perforation of the intestinal tract, or by puerperal infection, which tends to become general and rapidly fatal.

Gonorrhœal salpingitis has little if any tendency to spontaneous recovery. At best it results in the production of pelvic adhesions, binding the pelvic viscera together and producing pain, or interfering with the functions of the bladder or rectum. Usually the progress of the disease is from bad to worse, until the sufferer is reduced to chronic invalidism or dies from peritonitis or intercurrent diseases.

There can be no doubt that the condition of depressed vitality brought about by long-standing pelvic inflammation, and especially by the absorption of pus products, predisposes to the development of consumption,

[1] Read before the West Chester Medical Society.

and perhaps of other constitutional diseases. Cases of consumption have come under my observation in which pyosalpinx of long standing seemed to be the determining cause of the disease.

I shall not take up your time with a formal description of the familiar clinical history of this disease, but will report five cases somewhat in detail, in which the points of interest will be brought out.

Case 1.—Bilateral gonorrhœal salpingitis and ovaritis—So-called hysteria—Six attacks of pelvic peritonitis in five months— Removal of uterine appendages—Recovery.

Mrs. ——, æt. 20, multipara, always had good health, and was free from pelvic distress until March, 1887, when she developed an acute vaginitis with irritating leucorrhœa. This was treated with vaginal douches ordered by her physician without benefit. June 24, 1887, she was taken with pelvic peritonitis induced by salpingitis of the left tube. She had a severe attack, the temperature reaching 103° F., the pulse 110. Large amounts of morphia were necessary to relieve pain. After improvement had taken place she was sent to the seashore. While there she had two similar but less severe attacks, which, however, were accompanied with great pain. On one occasion it was necessary to etherize her, when morphia failed to relieve the pain. August 11, she came under my care suffering from mild peritonitis in the right side. Examination revealed intense vaginitis, a fixed uterus, and a tubo-ovarian mass in the right side. The temperature was 101° F., the pulse 90. At this time, I still clung to the old views of pelvic inflammations and expected to effect a cure with local applications. Rest in bed, sublimate douches, morphia and chloral iodine to the hypogastrium and liquid diet were prescribed. Under this treatment the woman improved very much. August 31 she was out of bed, felt well when quiet, and had a good appetite; but had pain on defecation and when jarred. Examination showed that the vaginitis was much better and that the uterus was more mobile. The tubo-ovarian mass was not recognized. Under depletion with glycerine tampons, and counter irritation with iodine, she felt quite well and vigorous again.

A fifth attack of peritonitis (salpingitis) supervened October 1. As before, the pain was intolerable. On endeavoring to relieve it I had an experience I shall never forget. Large doses of morphia were given hypodermically without bringing relief. On the night of October 13, after having given during the evening one grain and a fourth of morphia hypodermically in divided doses, about midnight I administered ether, hoping thereby to bring relief. Only a few inspirations were taken when the patient became "blue" and the respiration ceased. I believe that voluntary respiration did not occur for fifteen minutes—not until the husband had run nine blocks for a Faradic battery and this was got to work. Respiration immediately succeeded. During this interval artificial respiration had been kept up by Sylvester's method, while the head was dependant. The combined influence of the morphia and the ether had paralyzed the respiratory centre. After this event gradual improvement took place, and under advice of consultants, the former local treatment and general Faradization were employed. Tubo-ovarian masses could be felt on each side. During this time I determined that I would operate if another exacerbation occurred, and this did happen on November 3. After consultation with Drs. Kelly and Longaker, laparotomy was decided upon, and was done December 3, Dr. Kelly assisting. The appendages were removed without special difficulty; adhesions were general but easily broken up. The ovaries were enlarged, the left twice as large as the right; the tubes were dilated (pyosalpinx) and the fimbriated extremities were occluded. The operation was aseptic. No drainage was used. Convalescence was afebrile and free from incident.

This was almost certainly a case of gonorrhœal inflammation of the tubes and ovaries. The husband had gonorrhœa at the time, and he told me he had contracted it from his wife! There are two elements of doubt in the case. The woman was not virtuous, and hence her statements were not reliable; and besides the cervix felt as though it had sustained a laceration from a miscarriage or a dilating instrument, used, perhaps, to induce one. Unquestionably this woman endured a vast amount of uncalled-for suffering, besides running the risk of becoming a morphia eater. It would be interesting to know how many drachms of morphia she took; and, not less truly, how many useless visits I paid her, many of them in the night and at much cost to my personal well-being. This case was an education in itself. I

watched it until patient, family and physician were thoroughly disheartened. Operation was postponed on the advice of Dr. Wilson. Happily at this time women having gonorrhœa salpingitis of a serious character are subjected to operation without such useless delay. This woman made a perfect recovery.

Case 2.—Chronic salpingitis—Pelvic hematoma—Exploratory laparorotomy—Recovery.

Mrs. ——, æt. 33, twice married, never pregnant, always had suffered from dysmenorrhœa. Her first husband had gonorrhœa; but no distinct history of acute vaginitis in the patient could be obtained. November 6, 1886, after a long walk while menstruating she went to bed with severe pelvic pain and fever, in which her temperature reached 104° F., her pulse 120. A large mass formed in the pelvis occupying the left broad ligament and extending between the uterus and the bladder into the right broad ligament. A diagnosis of hematoma was made. She was kept in bed for six weeks and treated with quinine, anodynes and poultices, and later with counter irritation by means of iodine and blisters; internally she was given iodide of potassium and tonics. The hematoma was entirely absorbed. The uterus was left retro-verted and adherent, and a small tubo-ovarian mass could be felt on the left side. The woman resumed her laborious work, and became quite comfortable under local treatment, with iodine and glycerine tampons. In the fall of 1887 symptoms of subacute salpingitis supervened, and subsided under the same treatment, which was continued through September and October. June 26, 1888, the patient had an attack in every way similar to the one first narrated. The physical conditions were just the same, as was the treatment. July 15 the acute symptoms had subsided and she entered the Philadelphia Lying-in Charity. Here she was seen by Drs. E. Wilson, Parish and C. M. Wilson. The diagnosis was left in doubt: hematoma, pyosalpinx, cellulitis and ovarian tumor were suggested. Exploratory laparotomy was advised and done, Dr. Henry Leaman assisting. The patient was quite stout and her abdominal walls were at least 3 inches in thickness. It was necessary therefore to make the incision long enough to admit the half hand to explore the pelvis. The pelvis was found absolutely choked on the left side, with just enough space on the right side to pass two fingers behind the mass into the pelvis. The mass was clearly within the broad ligament, filling the left side, extending between the uterus and bladder to the right side of the pelvis; also along the left iliac fossa. It was everywhere hard. I considered that the diagnosis of hematoma was sustained, that this was not undergoing suppuration, and that, if it did, it could more safely be evacuated per vaginam, as no bowel was in the way. Drs. Wilson and Leaman agreed, and the incision was closed. No drainage was used. The deeper parts of the incision healed by first intention, but superficial suppuration occurred. When, a month afterwards, Mrs. —— was discharged, the hematoma was entirely absorbed and a small tubo-ovarian mass could be felt in the left side. She went home and to the wash-tub, and afterwards developed a ventral hernia. Since that time she has had one attack of acute salpingitis of the left tube. At the present time she is fairly comfortable, and therefore refuses operation for the removal of the appendages and the cure of the hernia.

The conditions present in this case are rare. Ante-uterine hematoma is rare, and ante-uterine cellulitis is equally rare. Unquestionably a salpingitis in the left side has been the cause of the hematoma. The inflammation is probably gonorrhœal.

Case 3.—Large pyosalpinx—Pint of pus—History extending over seventeen years—Operation in extremis—Recovery.

Mrs.——, aet. 36, mother of two children, aged respectively, fifteen and seven years, one miscarriage between labors, always well until marriage, at twenty years. At the first period after marriage she had a severe attack of pain in the left ovary, which the physician who was called in diagnosticated as due to ovaritis. There was no accompanying vaginitis. The husband had had a gonorrhœa with gleet for eighteen months, but had been pronounced well for some months before marriage. Sixteen months after marriage she gave birth spontaneously to a girl baby, had "chills and fever" and was four weeks in getting out of bed. Her physician said that "she came near having child-bed fever." She has never felt well since. Bearing down, leucorrhœa, dyspareunia and pain on locomotion supervened. Three months after labor an attack of salpingitis on the left side put her in bed for six weeks. Six months after labor she miscarried at the

second month, and within seven years she had six severe attacks of pelvic inflammation, each attack confining her to bed from four to six weeks. When the first baby was five years old an abscess discharged per vaginam. During the past seven years, since the birth of the second daughter, there have been three attacks of pelvic inflammation. Menorrhagia and metrorrhogia, leucorrhœa and pain in the left ovarian region have been almost constant. She has been in bed or "lying around" two-thirds of the time for sixteen years.

I saw her first in May, 1889. She was greatly prostrated and emaciated and was unable to walk. A large pyosalpinx on the left side was diagnosticated and its removal after preparatory treatment was advised. I was her eleventh physician, and she had been treated for everything except the real ailment. The appendages were removed at the Kensington Hospital for Women June 19, 1889, Dr. Hunter Robb assisting. The right tube and ovary were enlarged. The left tube was enormous and was ruptured during removal, discharging much pus into the peritoneal cavity—perhaps a pint. The peritoneal cavity was thoroughly irrigated and drained. Convalescence was slow. This patient is now, relatively speaking, well, and has gained twenty-five pounds. Champagne arrested obstinate vomiting on the fourth day after operation, and, I think, saved her life. The vomiting was bilious, dark green, and very offensive, with distinct fecal odor. It was apparently induced by a slight circumscribed peritonitis in the left inguinal region. The etiology in this case is obscure—the attack of ovarian pain during the first period following marriage is suggestive of gonorrhœal salpingitis. The cause, however, may have been puerperal.

Case 4.—Gonorrhœal salpingitis of six weeks' duration—Three attacks of pelvic peritonitis—Removal of appendages—Extensive intestinal and omental adhesions—Recovery.

Mrs.——, æt. 31, has had one child, has never miscarried and has always been well until her labor. She had a chill on the seventh day of her lying-in, but the very competent attending physician did not attribute it to sepsis. She was up on the twelfth day, but regained strength slowly. She contracted gonorrhœa in August, and had a severe attack of salpingitis of the left tube during her menstrual period in October. At this time she was under my care. A mild salpingitis of the right tube followed in two weeks, and at the period in November, she had a very severe attack.

Her sufferings were such that I was driven to operate during the continuance of the acute symptoms. This, I think, should not be the general practice, as the patient's vitality is already reduced by fever and acute pain and fatal shock is more likely to follow a serious operation. Laparotomy was done at the Kensington Hospital November 26, Dr. Boyd assisting. The omentum was densely adherent in the pelvis. It was partly torn loose and partly tied off. The appendages were densely adherent to all adjacent bowels from the cæcum to the rectum. The separation of these adhesions required much time and several ligatures. The pelvis being open, the right tube and ovary was freed from the cæcum and tied off, the left tube and ovary were then separated from the sigmoid and rectum and also removed. The peritoneal cavity was thoroughly irrigated and drained. The tubes were enlarged and contained creamy pus. Both ovaries were diffluent, from effused blood, and a hematoma was present in the mesosalpinx of the right tube. The patient went to bed much shocked, and was extremely sick for four days. The use of nutritive enemata, and the free exhibition of champagne, strychnia and digitalis hypodermically, together with such fluid nourishment as the stomach would bear brought her around. Convalescence was slow but quite satisfactory. At the present time she feels quite well and is rapidly gaining flesh.

Case 5.—Gonorrhœal salpingitis—Pelvic abscess—Operation—Recovery.

Mrs.——, æt. 28, married nine years, has had two miscarriages within the first year of married life. Six years ago she began to have labial abscesses, which have recurred four times. She has always had whites, but no history of acute vaginitis can be obtained. Shortly after marriage she began to have groin pains, which have troubled her all the succeeding years; but she has never been confined to bed until September, 1889. A feeling of soreness on exertion or jarring has been a constant source of annoyance. Dysporeunia also has been constant. Menstruation has been regular but always accompanied by severe cramps. Dysmenorrhœa was as marked before marriage as after. During September, 1889, after mov-

ing, a feeling of soreness in the pelvis, cramp-like pains, irritable bladder and painful defecation became very annoying, and persisted throughout the attack. Until Christmas she was sometimes better, sometimes worse; but after that time she was confined to bed. She now had chills, fever, tumefaction in the region of the left groin—in fact, all the symptoms of acute salpingitis.

I saw her first January 7, when she had a temperature of 102° F., chills, rapid pulse, tympany—in fact, all the symptoms of acute pelvic peritonitis. On examination a large tubo-ovarian mass on the left side, with evidence of general pelvic adhesions was found. A diagnosis of pyosalpinx was given, and operation after the subsidence of acute symptoms was advised. The patient was kept strictly in bed, and given quinine, a febrifuge, and morphia, sufficient to quiet pain. The bowels were kept loose with calomel or other laxatives. Poultices were applied to the hypogastrium. Under this treatment the acute symptoms rapidly subsided. Laparotomy was done January 30, at the Kensington Hospital for Women, Dr. Boyd assisting. As was expected, adhesions were general and dense. The omentum was separated from adhesions about the brim. The right ovary and tube was freed from deep adhesions and drawn up; when the cæcum was found adherent: the appendix being free. A large tubo-ovarian abscess, densely adherent to the pelvic wall, rectum and sigmoid, was found on the left side. The abscess was partly intra-peritoneal, as the bowel made part of its sac. The tube was, with difficulty, removed. The ovary, as such, could not be recognized. The peritoneal cavity was thoroughly irrigated with boiled water, and drained. Recovery was prompt, but for several days after the operation the woman was profoundly depressed. She left the Hospital after three weeks. The right tube is decidedly thickened, and the fimbriated extremity occluded. The left tube is much enlarged and elongated, and the extremity lost on the wall of the abscess.

These cases represent almost every phase of gonorrhœal salpingitis. In cases long neglected, more extensive peritonitis is present, and at times collections of pus form between agglutinated serous surfaces above the pelvis.

The cases reported were all treated by abdominal section, and in all but one the source of the disease was removed. In this case the complicating hematoma prevented extirpation.

The diagnosis of gonorrhœal salpingitis is based upon the symptoms and signs common to all inflammations of the Fallopian tubes. It is to be distinguished from the other varities of salpingitis either by the presence of a history of gonorrhœal infection, or by the absence of a history of other sources of infection.

The question as to the proper treatment of gonorrhœal salpingitis is one which demands our earnest thought. The natural history of the disease is now well known. Its tendency to progress from bad to worse, almost insures, in any individual case, a life of suffering, and invalidism, and final death from peritonitis. In view of these well-recognized facts, will it not be best to remove the uterine appendages by abdominal section early in the course of the disease, when the operation is a simple one, and comparatively free from danger? Operation done at this time will leave the pelvic and abdominal viscera in a comparatively healthy condition, and offer every hope of restoring health and usefulness. My own opinion is that such a plan of treatment is eminently and truly conservative, and I shall not hesitate to apply it whenever the conditions are such as to leave no doubt as to the diagnosis.

At the present time early operations are seldom done. The patient submits to operation only after repeated attacks of peritonitis, and perhaps after the formation not only of a pyosalpinx, but of intra-peritoneal accumulations of pus, and the matting together of some or all of the pelvic viscera. Operation done under such circumstances must necessarily often yield far from ideal results. The focus of the disease may be removed, but the secondary effects, local and general, not infrequently cannot be. In the more serious cases operation must be done with the purpose of saving life, and not with the purpose of doing a formal operation. In the worst cases it is enough if pus pockets be emptied and drained, for a formal operation, with separation of all adherent viscera and removal of the appendages, will require so much time and entail so much shock as to insure death.

Operation per vaginam is seldom indicated, and should be regarded as palliative rather than radical. In cases seen late, in which the vitality is so reduced as to leave little hope of recovery often abdominal section, in which the pus sac is adherent in Doug-

las's pouch, and in which early death is clearly to be apprehended unless the pus can be removed—in such cases I believe it to be good practice to operate per vaginam, to tide over the crisis. The pus should be evacuated by aspiration, the track of the cannula dilated, and a drainage-tube introduced.

The choice of the time of operation is very important. The history of these cases is that of many recurring acute attacks. Hence in any attack the probabilities are greatly in favor of improvement under the usual medical treatment. Therefore it should be the rule to wait for the subsidence of acute symptoms and some recuperation of strength before operating. In this way the patient will be better able to withstand shock. This rule, however, is not invariable, and operation must sometimes be done during the course of an acute attack to save life. To properly determine the right course all the knowledge, care and judgment of the surgeon is required.

SUPRAPUBIC LITHOTOMY. — PERINEAL LITHOTOMY.

BY JAMES B. THOMPSON, M. D.,
RATBUREE, SIAM.

On account of the interest taken in the suprapubic lithotomy, I will report a case in which I have performed the operation.

The patient was a man sixty years old, and he was operated on in November, 1887. I had for assistants the Rev. Mr. Dunlap and two of my native students. The man was of a spare build, somewhat emaciated from his sufferings, and, fearing that the stone was a large one, I decided to cut through the abdominal wall. A sound passed through the urethra guided me to the bladder wall, and the stone was easily removed, being only 1¼ inches in diameter. I closed the wound in the bladder wall with carbolized catgut, and inserted a small drainage-tube through the external wound into the sub-peritoneal tissues too, but not through the bladder wall. Oiled lint was applied as a dressing, and a soft catheter was left in the urethra for forty-eight hours. The patient was kept on his back (imperatively), with his head and shoulders slightly elevated. On the second morning the catheter was withdrawn, and the urine was voided normally during the day. The catheter was inserted again during the night. The drainage-tube was withdrawn by degrees, and on the fifth day was entirely removed. After the seventh day the catheter was dispensed with entirely and on the tenth the external wound was completely united. From that time on the man was allowed to sit up, and in four weeks he was perfectly well. Bichloride of mercury was the antiseptic used during the operation.

There are three features of this case to which I would like to call attention:

First—The bladder was not injected, nor was the rectum dilated. Prof. Agnew's suggestions in his *Surgery* seemed to me so thoroughly sensible that I determined to follow them. From my experience I feel satisfied that injecting the bladder for such an operation is a mistake.

The bladder wall can be found with greater ease when raised on the point of a sound than when injected. It is true the incising of the flaccid viscus is more difficult, but the round surface of the fundus when injected cannot possibly reach as high up towards the incisions as the sound would lift it.

Second—The wound in the bladder wall was immediately and completely closed. Some seem in doubt about this point and seem to prefer leaving it open *for fear some urine may get through it.* Isn't it more likely to extravasate if left open?

Third—The patient was kept on his back, with head and shoulders slightly elevated for eight or ten days. I cannot see the reasons which induce so many to place the patient on his side after such an operation. It seems to me that this invites urinary infiltration, while ostensibly providing for drainage.

In the after treatment of these cases perfect and speedy closure of the opening in the bladder is the great desideratum, and it does not seem rational to leave the wound ununited, or even with a drainage-tube between the lips, since both of these practices must certainly interfere with speedy closure. Then to place the patient on his side, the position which gives the greatest danger of even a small quantity of urine overflowing through the wound, completes the conditions required to bring about a high rate of mortality.

I would sum up thus: Use no injection, but be guided by the point of a sound through the urethra. Close completely the wound in bladder, but leave a drainage-tube in the external wound. If the bladder will

bear it, insert catheter per urethra for forty-eight hours. At least watch that the urine is withdrawn by catheter every two to four hours. Place the patient on the back with the hips lower than the shoulders, thus facilitating the flow of urine and rendering it possible for any accumulation of pus to escape through drainage-tube. I believe if these points are observed the suprapubic operation will be found more satisfactory.

I have had two other cases of stone which I cut through the perineum. The last one of the two I would have cut through the abdomen, but he took ether so badly—vomiting, etc.—that I did not dare to attempt it. The stone was $1\frac{1}{4} \times 2 \times 2\frac{1}{2}$ inches in size, and I greatly feared the boy would die from the difficulty I had in getting it through the bony structures of the pelvic outlet, but he recovered well and shows no evidence of any injury having been wrought.

FURTHER CONSIDERATION OF THE LATE INVASION OF THE GRIP.[1]

BY A. K. BALDWIN, M. D.,

NEWARK, N. J.

The peculiar heading of this paper is rendered necessary by the fact that at our last meeting, while the history, symptoms and treatment of the disease in question were thoroughly ventilated, it was determined to consider this subject again at our next gathering, which occurs to-night. Aware of the fact, as I am, that it may be impossible to impart any new information, it will probably not be amiss to compare notes with my fellow-practitioners in experiences in the concomitants, sequelæ and other after-results of this malady, which could not very well present themselves at our former gathering.

In order to speak of these more intelligently, it might be as well to detail briefly the grip symptoms.

These may be divided into three varieties:

1. *Nervous*, where severe headache, pain in the muscles of the eyes, frontal and supra-orbitory pain, usually of the left side, general neuralgic and rheumatic pain, more or less sweating, exhaustion and wakefulness prevail.

2. *Gastric*, where epistaxis, tonsillitis, nausea, vomiting, constipation or diarrhœa and dysentery occur.

3. *Respiratory*, where the whole respiratory system is invaded. The patient has pain in the frontal sinuses, the eyes congested and watery, profuse serous nasal discharge, and feeling of stenosis over the bridge of the nose, hoarseness, general bronchitis and severe angina.

All of these varieties may, of course, exist in one person and to such an extent that it may be impossible to distinguish the variety; or one set of symptoms may develop to be followed in turn by others. The duration of the grip has been found so variable that no distinct period of termination can be relied upon. Relapses and recurrences have been likely to occur, and many attacks of ordinary influenza that we now see are undoubtedly due to the semi-chronic inflammatory condition left behind. Cases of persistent neuralgia—cervical, facial and supra-orbital especially—are seen in our offices every day, and succumb only slowly to treatment.

While in the experience of probably all of us the grip *per se* has in no instance resulted fatally, we have seen dangerous concomitant or after-symptoms arise, which in a few cases have resulted fatally. Let us, however, not confound cases of consumption, Bright's disease, or any other grave disorder, with these sequelæ; since it is well known that the epidemic has intruded itself into any system irrespective of a pre-existing malady. Add prostration to that which already exists and an unfavorable prognosis is of course to be expected.

The long-continued prostration itself is grave and absolutely dangerous, and is a forerunner of extension of inflammation. That in the frontal sinus has been followed by meningitis, and death has occurred in a very short time.

General bronchitis has had added to it the capillary form. This occurs oftenest in females. The exhausted system is in about the same condition as that of young children who have been similarly affected. Should this form not remain dry the patient is unable to expectorate the large amount of secretion in the small tubes nature does not absorb, quickly, and death has occurred in some few cases from asphyxia.

But most frequent and fatal of all, where fatal results have occurred, has been pneumonia. It has been lobar or lobular in form, and generally catarrhal in character.

[1] Read before the Practitioners' Club of Newark, N. J.

The lower portions of both lungs have been affected. It has occurred more frequently in males. Commencing with a chill, it causes the sub-normal pulse and temperature to become accelerated and increased for the time being, until a profound condition of prostration exists. Even then, of course, most of our cases have slowly recovered; for persistency of all symptoms of the original disease and of its sequelæ seem to form a prominent feature of the grip. But some of our patients have slipped through our fingers and that, too, rapidly, in from two to five days, death being due to heart failure. While I have been fortunate with all of my cases—probably from giving very little treatment—having had my own business and partially that of two other physicians who were laid up with the fashionable disorder, I had serious apprehensions over several pneumonic cases which seemed to never get well; in fact, recovery, especially in one case, is not yet complete. May not this grave sequelæ, in feeble cases, be the foundation of phthisical lung disintegration?

In the gastric variety of the grip epistaxis, after occurring in the disease, has recurred so many times as to be an unpleasant symptom. I saw one such case; but this patient had had many attacks for months before. Dysentery, after most other symptoms had subsided, was present in two cases; but it was not persistent. Two cases of orchitis and epididymitis have interested me very much. In one case gleet was present and enlargement of the testicle had occurred six weeks before the attack of grip, terminating two weeks after commencement of the latter. Ten days after the grip symptoms subsided, severe inflammation of the testicles and epididymis again existed. In the other case there was no venereal history, and I am satisfied of the patient's truthfulness, as he has no object in deceiving me. In his case, however, rapid recovery followed. In the epidemic of 1732 swelling of the parotid glands and testicles was noticed occasionally.

Other symptoms and diseases have probably been met with by some of you as sequelæ of the grip; and, in fact, the question naturally arises: Are we yet entirely done with them? Compared with its ravages at its starting place south of St. Petersburg, the grip has been a mild disease in this country; but, from its extensive range, its sudden onset and its multitudinous victims, it may give us plenty of work with its sequelæ for some time to come.

PERISCOPE.

Cheyne-Stokes Respiration.

At a meeting of the Clinical Society of London, held Feb. 14, 1890, and reported in the *Lancet*, March 8, 1890, an interesting discussion took place on the subject of Cheyne-Stokes respiration. The discussion was opened by Dr. Samuel West reading the notes of a case of Cheyne-Stokes respiration occurring in the course of a case of granular kidney of three months' duration. The patient, a man fifty-three years old, with a history of gout occasionally, had been suffering from shortness of breath for eighteen months, especially after exertion. Six months before consulting Dr. West he was suddenly seized with very severe dyspnœa at night, so that he thought he was going to die. After half an hour he rallied, but he had two similar attacks in the course of a month, and then remained well until Feb. 14, 1890, when the worst attack of all occurred, since which time his breathing remained short. When first seen by Dr. West the patient had a pale, sallow, earthy complexion, with tortuous and thickened arteries, and a pulse of high tension. His pulse 104 and his respirations 48. The heart was not manifestly hypertrophied, and there was no murmur. The urine was of low specific gravity, 1.010, and contained about one-sixteenth of albumin. The retina was natural. The case was diagnosed as one of weak heart resulting from granular kidney. A few days later Cheyne-Stokes breathing developed. The respirations were 48 in the minute. The cycles occurred about once a minute and the pause lasted thirty seconds. There was no change in pulse, or pupil, or in appearance during the pauses. For fourteen days the Cheyne-Stokes breathing was continued night and day. Then the pauses disappeared and the general character of respiration was to crescendo and diminuendo. A week later the place of the pause was taken by intermission, about two or four respirations being missed. The heart was at the time observed to be gradually dilating and the apex was about the nipple; no systolic murmur was audible at the apex. A few days later the Cheyne-Stokes breathing, which had been absent for fourteen days, returned. After lasting twenty days, the pauses again disappeared. This condition lasted for four days, and then was replaced by Cheyne-Stokes breathing, which remained

present thenceforth until the patient's death. The cycles occurred over a minute, the pauses lasted from twenty to twenty-five seconds, and the respirations numbered about forty. For two days a ravenous, insatiable appetite developed, and then almost completely failed. The patient died after having been under observation three months. No *post-mortem* examination could be obtained. The temperature was normal throughout. The points of interest were: The long duration of the Cheyne-Stokes breathing; the replacement of the pauses by simple intermission; and the disappearance of the pauses while the rise and fall of the respirations continued. Dr. Charlton Bastian said that old writers had remarked on the association of Cheyne-Stokes respiration with fatty degeneration of the heart, but he had seen no such cases; he had observed it in connection with cerebral lesion. It might be, he supposed, produced by the blood poisoning associated with renal disease. Dr. Stephen Mackenzie had attended an elderly relative aged eighty, with dilated heart, granular kidneys and a little albuminuria, who showed signs of intermittent Cheyne-Stokes breathing for two months. He observed that at the commencement of the series of ascending respiratory acts a distinct movement of the arms towards the head took place. He had seen many cases in connection with cerebral disease, and he possessed a good chest tracing from a case of hemiplegia with diminished movement of one side of the chest. He had seen two patients recently in whom, during the apnœic period, a distinct convulsive seizure took place; one had between 150 and 200 such fits in twenty-four hours. He asked if any one had seen a case of Cheyne-Stokes breathing apart from injury of the head which had recovered. Dr. West said that the cases of Cheyne-Stokes respiration in association with fatty heart were easier to study than those associated with brain lesion. He thought it dangerous to lay much stress on convulsive movements in cases of unconsciousness. Oscillatory changes in the pupils were observed in other conditions, such as tubercular meningitis. One or two cases of recovery were on record, and in one a probably false diagnosis of tubercular meningitis was made.

In answer to Dr. Mackenzie's question, as to whether any observer had known a case in which this phenomenon was developed, to recover, Mr. R. H. Fox reports, in the same number of the *Lancet*, the following case:

The patient was a woman sixty-six years old, slight, delicate, and asthmatic, who was suffering from influenza and bronchopneumonia at the base of the left lung. The patient was thought to be dying. Delirium had been succeeded by drowsiness, alternating with periods of some mental activity. The right side of the heart was evidently much loaded, and the heart's action exceedingly irregular and jerky, but without bruit, temperature hypo-normal. The patient's hands were chilly and perspiring, the lips purplish red, the power of swallowing was almost lost, her cough was feeble, and expectoration, which had been lately abundant, had ceased—the general aspect betokened approaching dissolution. The respiration, which was attended with a rattling noise from mucus in the throat, and which had been irregular and labored, assumed and retained during one night the Cheyne-Stokes type. The respirations were shallow, brief, about 40 to the minute, and of diminishing force, until a pause came, lasting several seconds (perhaps ten); after this the breathing recommenced slowly. During the pause the pulse was unaltered, its rhythm being throughout very irregular, and the rate about 120 to the minute. The pauses varied in frequency, sometimes only six respirations came between them, sometimes much more. There was no apparent alteration of pupil. From this condition the patient recovered and has become fully convalescent, her recovery being attributable less to the digitalin, fresh infusion of digitalis, etc., administered, than to the gradual drying of the lungs by evaporation as she lay many hours almost without food or liquids, so that the heart was eased of its burden. No albumin or sugar was found in the urine.

Radical Treatment of Hernia.

In an article on the radical treatment of hernia, in the *University Medical Magazine*, April, 1890, Dr. D. Hayes Agnew says that the methods at present practiced are quite simple as compared with former ones, and while not free from danger, yet when done under strict antiseptic precautions furnish a very low mortality. Success, that is, a radical or permanent cure, is also claimed for a considerable proportion of the cases now subjected to the knife.

Dr. Agnew does not think that operators should commit themselves prematurely to

present plans, until both in time and in number, the necessary data for the expression of an authoritative opinion have accumulated. When we recall the enthusiasm with which the old Wutzer operation was greeted, and the scores of cures reported to have been made, and now consider that this procedure lives only among the surgical wrecks of history, the wisdom of this hint will be apparent—one, two or three years' observation of patients after operation will alone establish the verity of a cure. Indeed, any one who has followed the literature of the different surgical processes for the radical cure of hernia, and for most of which great success has been claimed, and then discovers that all have fallen into disuse, becomes naturally a little sceptical of the trustworthiness of surgical statements.

Dr. Agnew believes, however, that we are nearer the solution of the problem, that is, the permanent cure of rupture, than ever before, but he is not over sanguine as to its complete success. There are certain anatomical difficulties in the way which, while it would be rash to say that they are insurmountable, are certainly unfavorable to the accomplishment of so desirable an object. Not one of the structures used for fortifying the points of hernial egress can be said to offer as great opposition to intestinal protrusion as those normally existing, and the suturing together of fascia is at best uncertain in its results.

In formulating, as briefly as possible, his views on the necessities for operative measures looking to the permanent relief of hernia, Dr. Agnew states:

First. That the radical plan should follow all cases of strangulated rupture in which the knife has been employed for the relief of the patient.

Second. There are cases of hernia in the adult which cannot be controlled by mechanical measures, however skilfully applied. Fortunately such cases are not of frequent occurrence, but when met with, and the patient is not too far advanced in life, an operation should not be declined, as the risks from strangulation are greater than those from the knife. He certainly would not propose an operation in any case where the rupture can be perfectly retained by a truss, giving, as it does when properly fitted, so little inconvenience to the wearer.

Third. Children under ten years of age who have rupture are not proper subjects for operation. Such patients almost invariably recover after wearing a truss for two or three years. Not only so, but even in the event of strangulation occurring during these early years, and requiring an operation for the same, the subsequent use of a truss will prove to be no less efficient than had no such accident happened. This is just what might be expected, as the development which goes on with growing years naturally tends to consolidate and strengthen the hernial passages. When failure does occur, it is to be charged either to an improper, or badly-fitting truss, or to inexcusable carelessness on the part of the child or of those entrusted with the oversight of its life. The pad of the instrument should be a hard one, constructed out of deal wood or hard rubber. The entire apparatus must be adjusted with scrupulous care, fitting so neatly and evenly to the body of the patient as to cause no discomfort whatever. Nor should the truss be removed during the night, except for a short time, while the skin is becoming accustomed to the pressure, when it may be laid aside after the patient retires to bed. To render the surface of the body tolerant to the contact of the pad the parts should daily, for some time, be well rubbed with alcohol containing some alum, or with soap liniment. The necessity for this preliminary preparation rarely extends over six or eight days, after which the instrument must be worn night and day.

When from any cause the temporary removal of a truss is required, it should be done while the patient is in the recumbent position, and be replaced before rising to the feet. In addition to the instrument habitually worn, a second one ought always to be on hand for temporary use while bathing.

Surgery in Infancy and Childhood.

At the meeting of the Medical Society of London, held February 3, 1890, and reported in the *British Med. Journal*, Feb. 8, 1890, Mr. Edmund Owen delivered the third and last Lettsomian lecture, commencing with the operative treatment of the congenital form of wry-neck. He alluded to the risk of wounding some large vein, which was inseparable from subcutaneous tenotomy of the sterno-mastoid muscle, of which he mentioned an instance within his own experience. Since then he had relinquished this method of operating in the dark, and

had adopted the alternative plan of dividing the muscle through an open wound. The results of this plan had been fully as successful, and the uncertainty of the other method was avoided. He said that subcutaneous tenotomy was an anachronism in these days of antiseptic surgery, and he mentioned an instance in which it would have been impossible to have operated by the subcutaneous method without transfixing the internal jugular vein, though by the open method this was easily avoided. The lecturer then passed on to discuss the question of the treatment of vesical calculus in children. He observed that it might have been thought that finality had been reached when lateral lithotomy was brought to its present pitch of perfection, but he pointed out that under certain circumstances the operation presented difficulties and dangers it was impossible to provide against. He discussed Cheselden's statistics in the matter of lateral lithotomy, according to which this distinguished operator lost no more than three in 105 operations performed on boys under 10 years of age, but he added that his admiration for the operator was not equalled by his confidence in him as a statistician. He then took up the question raised by Sir Henry Thompson, as to what is a stone in the bladder. He first narrated two cases of what were often called "calculoid" disease, cases in which the stones were of small size and very apt to escape recognition by the sound, but he expressed the opinion that every concretion of a calculous character ought to be called a stone. He considered that the suprapubic operation was not the proper operation for the general run of calculous children, though it was at present the fashionable operation. He observed that it was unfair to submit the patient to the suprapubic operation, simply because the surgeon did not happen to possess Bigelow's instrument, litholapaxy being in many instances preferable. When the lithotrite could not be introduced, even after the meatus had been incised, and when the stone was not very large, as well as in those cases in which the stone, though not too large, was too hard to be dealt with by means of the lithotrite, lateral lithotomy was, he said, the appropriate method of treatment; with larger stones the high operation, as modified by Garson and Peterson, should be undertaken. Under these rules most children under two years of age would be treated after Bigelow's method, infants and a few grown children by lateral lithotomy, and in a few rare cases the suprapubic operation would be found necessary. In reference to the treatment of enuresis, he said he had found the internal administration of atropine to give good results. Passing on to the consideration of rupture in children, he urged that it should be regarded as a sign or symptom, rather than as a pathological entity, it being generally only a sign of arrested development in connection with the obliteration of the funicular process of the peritoneum. He dwelled upon the general precautions to be taken to prevent the increase of the rupture from violent expiratory efforts, etc., and advocated the employment of a skein of wool, so arranged as to afford support to the weakened side, in preference to any form of truss which, he said, was illsuited for children. Should the skein of wool prove insufficient, then a properly fitted truss would be necessary, but special care was incumbent in order to avoid undue chafing. He pointed out that most children lost the defect during the first year, though in others the cure might be delayed until puberty. He alluded to the causes of occasional erroneous diagnosis, and then passed on to consider the cases in which no truss could be relied upon to effect a cure. In these cases the duty of the surgeon was to bring about a cure, even if an operation had to be undertaken for the purpose. He held that the risks to which such a rupture would expose the patient in after life fully justified surgical intervention, though some judgment was desirable in the selection of cases for operation. He then described the steps of the operation, insisting upon the advisability of making assurance doubly sure by lacing up the lower end of the inguinal canal, especially the external abdominal ring with one or two strong sutures. He classed the subcutaneous methods of Wood, Wutzer and Spanton as empirical compared with the open plan of dealing with the defect, and he characterized the treatment by injection as incomplete and unsatisfactory. Alluding to the imprisonment of the testis within the abdomen, which was usually the result of any adhesion between that organ and the gut, he comforted himself with the reflection that such testicles were ordinarily undeveloped and of little utility. He concluded by saying that there were no cases of congenital reducible hernia in which he operated more readily than when there was an imperfectly developed testicle, for these

cases were well suited for treatment, and almost invariably completely successful.

Borax in Epilepsy.

At a meeting of the Cardiff Medical Society, reported in the *British Med. Journal,* April 19, 1890, Dr. Stewart, assistant medical officer at the Glamorgan County Asylum, related cases illustrating the value of borax in epilepsy. 1. A girl admitted, aged 13, had had epileptic seizures dating from birth, occurring in numbers varying from two to twelve per day and chiefly by night. She had been under treatment repeatedly, but without benefit. Without treatment the fits during the first week were twenty-six in number; under borax they were reduced to twenty-four in the second and eight in the third week. After an interval free from fits of sixteen days, four occurred on two successive nights; then after another interval of nine days a single fit took place, and since that there has been no recurrence of fits, that is, a clear interval of over a month. 2. This patient began to suffer from nocturnal epilepsy at eighteen and came under treatment five years afterwards. The case was complicated by serious cardiac disease and stenosis of the mitral orifice. Without treatment the average monthly number of fits were one hundred and one, and under borax this was reduced to twenty in the first month, seven in the second, one in the third, five in the fourth, none in the fifth, and one in the sixth. 3. This patient had whooping-cough at seven, followed by left hemiplegia, imbecility and epilepsy. The average number of fits a week, when no special treatment was employed, was three and one-half, and bromide failed to effect any reduction; after two and a half years' treatment the weekly average had risen to sixteen. Under borax the weekly average during the first month was reduced to fifteen and one-half, and during the second month to eleven and one-half. The diminution took place chiefly in the nocturnal seizures. In 4, 5 and 7, in which the fits occurred both by day and night, bromide exercised a decided influence upon the diurnal seizures, leaving the nocturnal practically unaltered, and in these benefit was experienced from the combined use of bromide and borax, three doses of the former during the day and one single dose of the latter at bedtime. 6. This patient, epileptic and imbecile from birth, came under treatment at thirty-five. The fits were of the nocturnal type, were uninfluenced by bromide, and were slightly diminished by borax.

Dr. Stewart concluded that borax exercised a peculiar influence over nocturnal seizures, and that it was in cases where the fits were entirely of that kind that the greatest good might be expected; that bromide, on the other hand, exerted a more powerful influence over diurnal seizures, and that in cases characterized by both day and night fits a combination of these two remedies would be productive of most benefit.

Turning in the Genu-Pectoral Position.

Writing to the *British Med. Journal,* April 19, 1890, Dr. Edwin T. Ensor says: I was called some time ago, by an experienced midwife, to see a primipara in labor at term; she saying a hand was presenting. I found not only a hand but also a foot and the head, the last being impacted in the pelvis, having forced down before it the posterior segment of the partially dilated os and cervix uteri, which it was injuriously compressing between itself and the promontory of the sacrum. The membranes had been ruptured a long while before I saw her, and the uterine contractions were nearly incessant. Patient declined chloroform and, being on her left side, after attaching a tape to the presenting foot, I did what I could with the left hand in the vagina towards pushing the head above projection of sacrum, but without success. It then occurred to me that if I put her in the knee-chest position, so as to allow the womb and its contents by virtue of their weight to fall forward and downward, turning might be made easier. This I did, with the satisfaction of finding that I was enabled to complete the operation with the greatest ease imaginable; very slight pressure of the head with simultaneous traction on the leg being alone required. The child, which was of average size, was as might have been expected, stillborn.

Dr. Ensor adds that he is not aware if this method has been suggested or practiced in similar cases before, and that he reports his case in the hope that the plan he adopted (which the readers of the REPORTER know is not novel) may serve others as well as it has served him.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

CODEIN AS A SUBSTITUTE FOR MORPHIA.

The *Deutsche med. Wochenschrift*, March 27, 1890, contains a reference to the favorable results obtained by Kobler, in the wards of Prof. v. Schrötter, in Vienna, from the use of codein, as a substitute for morphia, to control cough dependent upon bronchitis or tuberculosis of the lungs. Codein appeared to diminish the expectoration in some cases. Kobler gave it in doses of from 0.03–0.04 grains (1/6–1/2 grain) using each day from 0.1–0.15 grains (1½–2¼ grains).

At the meeting of the Medical Society of Berlin, March 17, 1890, as reported in the *Deutsche Medizinal-Zeitung*, March 27, Loewenmeyer reported a number of experiments which he had made in the Jewish Hospital, at the suggestion of Prof. Jacobson, with codein as a substitute for morphia. In the course of a year he has administered about five thousand doses to about four hundred patients, to some of whom it was given for weeks and even for months at a time. The conclusion arrived at, in a very large series of experiments, was that codein was a remedy analogous in its effects to morphia without its unfortunate results. The remedy was administered in various disturbances of the abdomen and pelvis, and in most of them the result was entirely satisfactory. The patients had some hours of rest from their pains, and slept. When the pains returned, the codein being repeated produced the same effect as before. In cases of pain depending upon serious physical alterations —as in cancer of the stomach—the result was not always the same. Sometimes the pain was assuaged; but in a large number of cases its results were unsatisfactory. In this respect Loewenmeyer estimates the value of codein, compared to that of morphia, as being as 50 or 60, or as 90 to 95. It was observed that the administration of codein for paroxysmal pains of great intensity was not followed by satisfactory results. This was noticed in cases such as those of gall-stones and kidney-stones. The use of codein proved especially satisfactory because it seemed to be entirely free from any deleterious influence upon the organs of the body, and never produced anything which could be called "codeinism;" and it seemed to be especially adapted for cases in which a remedy must be used for a long time.

The most satisfactory results in the use of codein was found in the treatment of diseases of the chest and respiratory organs. In phthisis the sense of oppression, the stitches in the side and the painful cough were controlled permanently by the use of codein; and in such cases Loewenmeyer was able to dispense entirely with the use of morphia. In cases of bronchial catarrh, pleuritis and pneumonia, codein was used continuously with good success. The same

was true in cases of pulmonary asthma. Patients who had come to regard their unfortunate condition as beyond improvement learned to use codein when they felt an attack coming on, and thereby shortened their attacks and diminished their pains very considerably.

In cases of heart disease toxic effects were never observed from the use of codein, and in many cases of disturbances of compensation codein produced unmistakably good effects.

In diseases of the nervous system codein did not prove to be of any very great value; and irritation originating in the brain or spinal column, as well as that originating in the peripheral nerves was not amenable to treatment with this drug. In cases of simple insomnia codein proved to be a very valuable remedy; and Loewenmeyer suggests that it would be useful as a substitute for morphia in cases of opium habit. The doses administered varied between three and five centigrams (half a grain to three-quarters of a grain). Where these doses were not sufficient, larger doses were found also to fail. Such doses were given from three to five times a day, and were continued in some cases for weeks and months without any unfavorable results. The codein was generally administered in the form of a powder, or in a mixture made up with a syrup. It was also used in the form of suppositories.

These results may encourage medical men to test for themselves the value of codein as a substitute for morphia. This will not be a new venture; for codein has often been used in this way before, with varying, and often contradictory results. But, with the experiences cited above to guide and encourage them, medical men may with good hope of succcess try the effect of codein as a substitute for morphia in a considerable number of ailments; and it may be that they will find it to be of much greater value as a hypnotic than they have hitherto supposed.

TUBERCULOSIS BY INOCULATION.

Koch's discovery of the tubercle bacillus has facilitated the diagnosis of obscure cases of tubercular diseases and has been followed by numerous reports of tuberculosis from inoculation. In the majority of these one point has by no means been indisputably proved. It has been clear that a wound of an apparently healthy patient had become tuberculous, but the origin of the virus and the process of infection has been only hypothetically explained. In some cases it may be claimed that the subject was tuberculous before receiving the injury and that the local infection was from within and not from without. In other cases it seems that the infection came from without. Foremost among the latter are the cases which have been reported by Lehmann, Hofmokl and Elsenberg, in which tubercular infection followed the Jewish ritual of circumcision; the custom of sucking the wound being practiced among the lower classes of Jews in Germany, and the infection being clearly traced to phthisical circumcisors.

The course of the disease after inoculation seems to be analogous to the course of tuberculosis as experimentally produced by inoculation in the lower animals. The wound at first heals; after a few weeks the cicatrix becomes hard and assumes a bluish-red color, and then changes gradually into a characteristic tubercular ulcer; this is followed by involvement of the neighboring lymphatic glands and later the more remote glands; then general infection comes on and finally death.

The above course was followed exactly by a case of tuberculosis by inoculation, reported by Dr. T. Deneke to the Medical Society of Hamburg, and quoted in the *Deutsche med. Wochenschrift*, March 27, 1890. The patient was a female infant, seven months old; and when first seen was in perfect health. The mother had applied to Dr. Deneke, to ask whether it would be advisable to continue to nurse the child, as she (the mother) had recently acquired a

cough and felt unwell; although, to all appearances, she too seemed in excellent health. She was advised to wean the child at once. A few days later Dr. Deneke was called to see the mother, who was suffering from slight hemoptysis. He observed at the time that the woman expectorated in a pot at the side of the bed. A few days later the infant fell out of bed and struck its head against this vessel, which broke. The child received several superficial cuts from the sharp edges and lay on the floor among fragments and sputum. The child was immediately taken to Dr. Deneke, who washed the wounds with sublimate solution and applied iodoform collodion. Within a week the cuts had completely healed.

Six weeks later the scars became swollen and assumed the typical bluish color; there was also a painful swelling of the left parotid gland. Gradually the characteristic features of tuberculosis became more pronounced; surgical interference was resorted to at an early date; and, although at first seemingly successful, was later of no avail, the malignant character of the disease being all too evident; and the child finally died, six months after the original injury. The autopsy is said to have precluded the idea of any other infection than the one mentioned.

It is well known that while the principal surgical antiseptics now in use may destroy the micro-organisms which usually cause traumatic infection, yet their immediate effect upon tubercle bacilli is very uncertain. It has been demonstrated that twenty-four hours are necessary for the sterilization of tuberculous sputa in a five per cent. solution of carbolic acid. Sublimate solution has also proved itself untrustworthy as a means for the immediate sterilization of the tubercle bacilli in the sputum.

While Dr. Deneke's theory of the child's inoculation is very plausible, it is not conclusive. It is quite possible, considering the intimate relations of mother and child, that the inoculation of the wounds may not have taken place at the time of the injury, but at some other time and in some other way.

TREATMENT OF PLEURAL EFFUSIONS.

Pleurisy in a large number of cases results in the formation of fluid, which varies in amount, and, while generally serous, may be purulent. The object of treatment is to remove the cause of the effusion, which is usually an inflammation of the pleura, and get rid of the effusion itself. To accomplish this object the patient is kept in bed and as much rest secured to the inflamed pleura as possible. Further, the various emunctories and absorbents of the body are stimulated to carry off the fluid. A pill composed of calomel, squill and digitalis has been much used. The salts of potash, especially the citrate, acetate and iodide, are also highly esteemed, and so are the tincture of the chloride of iron and jaborandi. Large fly blisters have also given good results in some cases. A more effective treatment consists in the administration of frequently repeated doses of Epsom salts in a very small quantity of water, while the patient is deprived of fluids to drink. The Epsom salt causes large watery evacuations from the bowel, but it is manifestly too exhausting for any but a robust subject.

If judicious medical treatment fails to effect the removal of the effusion, it must be accomplished by surgical measures. For a long time the propriety of withdrawing the fluid was considered doubtful, but thanks to the successes achieved by Trousseau and Bowditch, to the improvement by the latter of the aspirating apparatus, and also to the general recognition of the vital importance of surgical cleanliness, aspiration of a pleural effusion is now a very safe operation and one which is demanded imperatively under certain conditions.

How long should one wait for the absorption of a pleural effusion before removing it by operative means? To this question scarcely any two persons will give the same

answer. Some are inclined to defer the operation for a month or six weeks, others to operate within ten days. When one considers the effect upon the lung of compression against the spine, and that the longer it remains in that condition the greater is the probability that adhesions will form to prevent its subsequent expansion, while during this time the patient suffers much discomfort and is exposed to the risk of syncope—it would appear evident that it is far wiser to err on the side of an early operation. We believe that a serous effusion which shows no sign of decrease in volume within ten days or two weeks should be aspirated, even though there has occurred neither syncope nor great dyspnœa. The occurrence of the latter symptom is almost universally regarded now as an imperative indication for operation, and many hold it to be so even if the effusion is not sufficient to fill the pleural cavity. Other conditions which demand prompt operation are the coexistence of pericardial with left pleural effusion, of double pleural effusion, a murmur at the base of the heart due to a twist of the aorta, and, of course, of a purulent effusion. It is not sufficient objection to paracentesis to say that so long as the inflammation of the pleura persists the fluid will reacoumulate as soon as it is withdrawn, for the operation will give the lung a chance to expand, so that it will be less likely to be permanently injured than though it were kept compressed continuously; and this is one of the most important objects of the operation.

In purulent pleurisy operation should be resorted to as soon as the diagnosis is made, provided that the condition of the patient at all warrants the operation. Generally aspiration alone is insufficient, except, perhaps, in children. Two openings may be made and a fenestrated rubber tube passed through, so as to secure complete drainage and permit of thorough washing out of the pleural cavity; or resection of one or more ribs may be necessary to obtain sufficient room for drainage and irrigation. The result of either operation is very unsatisfactory, especially in hospital practice.

A favorite point for puncture in paracentesis is in the sixth or seventh interspace at about the posterior fold of the axilla. If the patient cannot be moved easily it may be better to puncture in the mid-axillary region. The amount of fluid to be withdrawn will depend upon the judgment of the operator as regards the effect produced upon the patient. The occurrence of much cough, dyspnœa, a sense of constriction, or of syncope is generally regarded as a warning to withdraw the needle. When a portion of the fluid has been withdrawn, nature frequently shows herself competent to get rid of the rest.

When sufficient fluid has been aspirated to meet the indications of the case, the needle should be pulled out rather quickly. The tissues will come together and prevent the entrance of air, but it is better to dust the point of puncture with iodoform and apply over it a piece of adhesive plaster. If the needle and the skin have been rendered aseptic before the operation and reasonable care is exercised after it, there is almost no danger from it.

CLOSTRIDIAL NEPHRITIS.

In the *Pacific Medical Journal*, April, 1890, Dr. F. V. Hopkins, of San Francisco, records, under the title of Clostridial Nephritis, the fatal case of a female patient, with flatulent dyspepsia, sleeplessness, nervousness, dyspnœa, weak heart, dropsy and albuminuria. An autopsy was not permitted. The urine contained bacteria: cocci, bacilli and spores, free and attached to tube casts, which were also present. Eight varieties of albumin were found. Cultures of the bacteria injected into the peritoneal cavity of rabbits produced ascites and a fatal issue; and on section the micro-organisms were found in the arteries of the lungs and kidneys of the animals.

The writer admits that a single case and a

few inoculations do not suffice to establish the independence of a distinct disease or of a specific bacterium. The three requisites of the latter are: 1. its constant presence in all cases; 2, its culture in artificial media, with reproduction of its kind; 3, production of the like disease by inoculation. In the experiments related these conditions have not been fulfilled. It is not stated how soon after voidance the urine was examined, nor whether or not it contained pus in addition to albumin and casts. Recent normal urine contains no bacteria. With the occurrence of alkaline fermentation, however, cocci, rods, spirilla and spores may be found. Bacteriuria has also been observed in infectious diseases and in cases of genito-urinary disease. Cystitis is not uncommon in females, and the urine may readily be contaminated from leucorrhœal discharge. If modern bacteriology has established any one point it is that specific bacteria are not polymorphous, and that they do not appear interchangeably as cocci and bacilli. Nor is it shown, in the experiments reported, that the inoculations gave rise to nephritis. The ascites may readily have been due to a traumatic or to a septic peritonitis.

On looking over the report before us we do not see any sufficient reason for thinking that Dr. Hopkins has described a new disease or that he is even warranted in his assumption that Koch agrees with the classification of the micro-organism he describes.

We refer to the matter in order to record the investigation, without committing ourselves to the opinions founded upon it by the investigator.

Philadelphia Hospital.—The summary changes made last December in the Visiting Staff of the Philadelphia Hospital were fully discussed at that time in the Reporter. The latest development in the matter is that the Court of Common Pleas on May 17 granted an alternative writ of mandamus on the Mayor and Heads of the Municipal Departments, commanding them to make rules for appointment or promotion in the medical staff of the Philadelphia Hospital.

New Remedies and Appliances.

In this department, notice will be given of Remedies, Food Articles, and Instruments or Surgical Appliances of which specimens are sent to the Editor; it will bear the same relation to these articles that the department of Book Reviews now does to books.

A specimen of Van Houten's Cocoa has been tested by actual use and found to possess the advantages of concentration and aroma claimed for it by the manufacturers. When made according to the directions, is a very agreeable and nutritious beverage—the preparation is simple and easy, and does not require the addition to the cocoa of milk, water being the solvent called for. For children and invalids cocoa is a valuable article of food, and for all persons it is a wholesome beverage.

Correspondence.

Foreign Physicians in France.

To the Editor.

Sir: An Editorial in your number of April 12, 1890, on "Foreign Physicians in France," in so far as your remarks in regard to American physicians practicing in France not having restrictions placed upon them, induces me to reply that *all* foreign physicians are expected to conform to the French law which insists on certain examinations being passed before entry into practice here.

Some years ago the Minister of Public Instruction used his right to give to foreign physicians permissions to practice, but this led to an abuse and to much recrimination by the French doctors who spoke English and found their practice encroached upon by foreign doctors. On their complaining to the Minister he gave the matter over to the body called *Le Conseil superieur de l'Instruction Publique.* In point of fact he simply sends the diplomas, presented by foreign doctors who wish to practice in France, to the Faculty of Medicine, to decide how many and what examinations they should pass. The new law about to be passed and acted upon now says: "All doctors who pass their examinations abroad, no matter what their nationality may be, cannot practice their profession in France unless they pass the examinations here according to law. Certain examinations will be omitted by the Minister of Public Instruction after the Su-

perior Council shall have advised him of the value of the diplomas presented, but in no case will all the examinations be omitted." Every applicant must pass some examination to show his ability as a doctor.

However, exceptionally, a doctor, *who lives and has his residence in his own country*, can be allowed an authorization to accompany a patient of their own nationality to the watering and winter stations of France, and to treat them for one year. This permission is only for one year, and can be revoked at any time.

This is the substance of the law, and the effect of it is that all foreign physicians must pass an examination if they wish to practice in France.

The Faculty of Medicine at Paris has a full and correct list of the schools of medicine all over the world, and they give a fair allowance to all recognized diplomas. The requirements here are four years' study and five examinations and a thesis. The examinations are each divided into two, and really make *ten in all*, and most French students take from six to seven years to do them.

As regards American diplomas, they are rarely counted for more than the first examination here, and American doctors are now asked to pass the four final examinations.

The English diplomas fare better, and they get two or three of the examinations off. Seldom more than three.

As regards the number of English and American physicians in practice in France, it is considerable, over twenty (22) in Paris alone, and from four to five in each of the watering-places, so that English-speaking people do not lack the attention of a doctor of their own race, and as there is always a certain number passing examinations and studying medicine in France, the supply is kept up.

Yours truly,

THOS. LINN, M. D.,

Paris, France.

State Board of Medical Examiners.

TO THE EDITOR.

Sir: The REPORTER of March 15 contained an abstract of a paper by Dr. John B. Roberts, read before the Jurisprudence Society on the necessity for an Examining Board, in which the conclusions of the writer in some particulars do not seem to convey the sentiment of the profession. He says: "Of course such a board, to be just, should not be expected to recognize any sort of medicine; there should be no mention or allusion in the law to special doctrines or special methods of practice. The present bill is framed with this as its underlying principle; and is equally fair to all forms or systems of practice, all of which have the same right to be represented in its composition."

We had hoped those who were interested in the effort to secure the passage of the proposed bill at the last session of the Legislature had profited somewhat by their experience, and if a repetition of the attempt were contemplated we earnestly desired the preparation and presentation of a bill that would deserve and command the support of the true profession. The indications, however, do not seem to favor this hope if the tenor of the extract we have just quoted from Dr. Roberts is to be accepted as a prelude. If this specimen of how not to do it is the "underlying principle" of the bill, nothing further, perhaps, need be offered to show that such a bill should not become a law.

If veritable sects in medicine had an existence they should be mentioned in the bill and proper disposition should be made of them.

As special schools or sects, however, exist only as a pretence, care should be taken to dispose of them accordingly, and no bill should be contemplated without distinct provisions on this very point. That there should be no mention or allusion in the law to special doctrines, special methods, schools or sects, while at the same time declaring that they all have a *right* to be represented in the composition of the board, partakes entirely too much of the "now you see it and now you don't" method.

To attempt the disposal of the pretended sects and schools by jugglery, is perhaps somewhat according to the method of *similia*, but we have had too much of this in former efforts at medical legislation.

True medicine, or a system upon a basis of demonstrated truth is the only system for legislative contemplation. The best means of the application of these truths is the method of the true physician. This is the only *system* and the only *method* for legislative contemplation. Any other so-called system is a pretence, any other so-called physician is a pretender. In the field of true medicine is embraced all medical truth, no area of truth remains as a basis for any other system or sect. Truth needs but to

be demonstrated to be accepted as the basis of this system.

Truths of the method of practice are all susceptible of demonstration, and need not and should not be accepted as the basis of a system until so demonstrated. There are no contradictions nor need there be even diversity of opinion in a system upon a basis of truth demonstrated. Truth never contradicts truth. Upon this basis there is no motive for partiality; truth is accepted from any source; *similia* truth is as acceptable as *contraria* truth; the truths of Hahnemann or of any other man are included in true medicine. There is no other form or system of medicine or method of practice for legislative contemplation. This is the "underlying principle" for a proper Examiners' bill, and a principle that can be comprehended by the average legislative mind even in the absence of either scientific or medical knowledge. If the contemplated bill has for its object the protection of the public against dangerous ignorance in those who are permitted to practice medicine, this is the "underlying principle" that will need to be observed.

Instead of contemplating an "underlying principle" that shall be "fair to all forms or systems of practice," the advocates of the necessity for an Examiners' bill should contemplate the "underlying principle" that should secure education in medicine; education in the practice of medicine upon a basis of truth, demonstrated and unmistakable truth, with no other name and in no other form.

As the fundamental truths of a method of practice are susceptible of demonstration and all demonstrated truth belongs to, and is embraced in true medicine, these pretended forms or systems of Dr. Roberts are without a basis of truth and without truth in their methods.

As so-called schools, sects or special methods of practice have not been created by Act of Assembly and have no existence or standing in law, the authority for their existence contemplated by Dr. Roberts is of some interest. They are a pretence, and the only authority for their existence is the *ipse dixit* of the pretenders themselves, and of their dupes. The law has not created an allopathic, homœopathic or any other system or school of medicine, nor need they be contemplated in framing an Examiners' bill.

These pretenders assert that schools exist, and they demand legislation to suit their purposes, while the State Constitution distinctly forbids that form of legislation. The Constitution of the State declares that the General Assembly shall not pass any special law granting any special privilege to an individual or a corporation.

Any law creating an Examiners' Board will be null and void unless the methods of the last attempt be altogether reformed.

Yours truly,

S. Updegrove, M. D.

Philadelphia.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

SAUNDERS' QUESTION COMPENDS. Essentials of Diseases of the Skin, including the Syphilodermata. Arranged in the form of questions and answers, prepared especially for students of medicine. By Henry W. Stelwagon, M. D., Ph. D., Dermatologist to the Philadelphia Hospital, etc. With seventy-four illustrations. Small 8vo, pp. 262. Philadelphia: W. B. Saunders. 1890. Price, $1.00.

The publisher of the present excellent series of compends is fortunate in having secured so competent a person to write a compend on diseases of the skin. From the well-known ability of the author the scientific part of the book may be assumed to be accurate and up to date, and we have satisfied ourselves that the questions and answers are brief, clear and to the point. The preservation of the Latin forms of the names of the skin diseases might be objected to as undesirable in a compend. Under the treatment of ringworm we are surprised to see no mention of tincture of iodine, one of the most valuable remedies; this, with the application of a solution of iodide of potash in liquor potassæ, followed by one of corrosive sublimate in ether, or spirit of nitrous ether, will cure more chronic cases of ringworm than any other remedies. It is severe, but not poisonous.

This criticism is not intended to detract from the great merit of the book; it is an excellent book written by a thoroughly trustworthy man, and we cordially commend it to our readers.

MAY'S DISEASES OF WOMEN, being a concise and systematic exposition of the theory and practice of gynecology. For the use of students and practitioners. Second Edition, revised by Leonard S. Rau, M. D., Attending Gynecologist to Harlem Hospital, Out-door Department, New York, etc. With thirty-one illustrations on wood. 8vo, pp. 373. Philadelphia: Lea Brothers & Co. 1890. Price, $1.75.

May's Diseases of Women is a compilation from the writings of various distinguished men. The author, in his original preface, made no claim to originality, and Dr. Rau, in preparing the present edition, has kept in view the original scope of the work. As it stands now, the book is a closer approximation to current teaching by the best men than its predecessor, but in a number of points it is behind it; the latter is es-

pecially true of chapter XII, on "Affections of the Pelvic Connective Tissue."

The book is written in a plain, straightforward, clear style, and is handsomely printed. It fulfills a useful purpose, and is, in the main, what it claims to be.

Notes and Comments.

Tenth International Medical Congress.

By direction of Count Arco, the German Ambassador in Washington, the Consul General of the German Empire in New York, Mr. A. Feigel, sends the following, with the request that the medical and secular press of the country give it the greatest possible publicity. It will be noticed that this circular contains a great many particulars not contained in those previously printed.

CONDITIONS AND RULES REFERRING TO THE INTERNATIONAL MEDICAL AND SCIENTIFIC EXHIBITION IN BERLIN, AUGUST, 1890.

I. The Exhibition will be opened 11 A. M. on August 2, 1890, and closed, probably, August 11, P. M., in the Landesausstellungs Park; the sections of the International Medical Congress will meet in the same place.

Provisions will be made for dark chambers, rooms for experimental purposes, and appropriate demonstrations by experts.

The Exhibition is limited to the following objects: New or improved scientific instruments and apparatuses for biological and strictly medical purposes, inclusive of those for photography and spectral analysis applicable to medicine. New pharmacological, chemical and pharmaceutical materials and preparations. New foods. New or improved instruments for operations in medicine, surgery, special branches, electrotherapy, etc. New plans and models of hospitals, convalescent homes and establishments for disinfection and bathing, arrangements for nursing and transport. New hygienic apparatuses. New tables and charts of a statistical nature. Preparations and models. Teaching apparatuses. Medical literature.

Applications are expected before May 15, 1890,[1] and will be received by the Secretary General of the Congress, Dr. Lassar, Berlin N. W., Karlstrasse 19. They must be marked "Ausstellungs Angelegenheit" and accompanied with a printed visiting or business card containing name and address.

II. Of each application there ought to be two copies. It is requested that it should contain a brief and accurate description fit to be used in the compilation of the catalogue.

III. The decision as to the admission of all or part of the proposed exhibits rests with the special or general boards of organization; they will send an immediate reply.

IV. The cost of every square meter or part of a square meter of floor or table surface is 10 marks, of wall surface 6 marks. Two (2) meters in height of the wall are free for those adjoining the wall. Exhibits in the interior of the hall pay for one-half of the size of the walk immediately surrounding, in addition to the space occupied.

V. Tables will be furnished. Cases, shelves, repositories must be procured by the exhibitors under the supervision of the Committee. Electric light, steam power, etc., can be had by special arrangement.

VI. Inflammable objects are excluded. Insurance of those admitted will be secured free of cost, if notice of their value have been given.

VII. Packing and unpacking is free of expense to foreigners. Great care will be taken but no responsibility. Expressage by Messrs. Jacob und Valentin, Berlin O. Holzmarkt-strasse 65.

VIII. The exhibits must be delivered on or before July 20. Foreign goods will be free of duty, but certificates—to accompany the goods—ought to be obtained from the exhibition office, Karlstrasse 19.

FORM OF APPLICATION.

The undersigned being acquainted with the conditions and rules referring to the International Medical and Scientific Exhibition in Berlin, August, 1890, requests admission for the following exhibits:

SPACE WANTED { Floor surface Length Breadth / Wall surface Breadth Height

Exhibition will take place

(a) in own case: adjoining the wall?
inside?
(if the latter add a diagram)

[1] Count Arco has made such arrangements that applications coming from the United States will be received until the first of July.

(b) on tables to be furnished by the Committee
in flat cases?
exposed without them?
on shelves?
the wall surface above the table is required to the height of?
(c) on the floor, without case, etc. ?
(b) as drawings, diagrams, or in narrow cases attached to adjoining walls?
VALUE for insurance purposes.
SPECIAL REQUESTS.
BRIEF NOTES for Catalogue.
Name, etc.
1890.

The Bucks County Medical Society.

The Bucks County Medical Society of Pennsylvania had its semi-annual meeting May 7, 1890. Delegates to the State Medical Society were elected as follows: Drs. J. H. Krause, Q. L. Adams, A. M. Cooper, R. C. Foulke, H. Pursell, J. N. Richards, S. H. Wilson and M. B. Dill. Dr. Hiram Corson was present and spoke on the management of State Hospitals for the Insane. The Society adopted the following resolutions:

Resolved, That the Bucks County Medical Society recommends that the Superintendents of Hospitals for the Insane be relieved of all duties and responsibilities not strictly professional in their character and that all non-professional services be devolved upon the various boards of trustees, where they properly belong; and further,

Resolved, That this Society recognizes the fact that there are within the ranks of the profession many female physicians not inferior in attainments and ability to their brethren, and believes that if there is any special field in which the knowledge and skill of our professional sisters should especially be employed, that field will be found to lie among their own sex; and, hence, this Society advocates and advises the employment of competent women doctors to take charge of the wards for female insane in all the asylums of this State.

Dr. Thomas L. Allen read an essay on "Compound Dislocations of the Ankle-joint." The essay was discussed by Drs. A. M. Cooper and Joseph B. Walter. Dr. S. H. Wilson read an essay on "Some Lessons of La Grippe." The paper was discussed by Dr. Q. L. Adams, Dr. A. M. Cooper and Dr. Joseph B. Walter. Dr. H. Pursell read an essay on "Suppurative Orchitis." The president appointed as essayists for November, 1890, Dr. Q. L. Adams and Dr. A. F. Myers. The next meeting will be held at Bristol in August.

Ohio Medical Society.

The forty-fifth annual meeting of the Ohio State Medical Society will be held at Columbus, June 4–6, 1890.

The following papers are announced:

Errors of Refraction and Muscular Adjustment as Causes of Nervous Phenomena; C. F. Clark, Columbus; Cleanliness in Eye Surgery; B. L. Millikin, Cleveland; Carcinomata Mammæ; their early Diagnosis and Operation; Dudley P. Allen, Cleveland; A Further Study of Hernia; A. W. Ridenour, Massillon; Vaginal Extirpation of the Uterus for Cancer, with Report of Cases; C. A. L. Reed, Cincinnati; Vaginal Hysterectomy; A. B. Carpenter, Cleveland; Report of one Year's Work of Intra-Pelvic Surgery for the Relief of Inflammatory Diseases; R. B. Hall, Cincinnati; The Etiology and Treatment of Pneumonia; S. P. Deahofe, Potsdam; The Surgery of the Knee Joint, with the Report of Cases of Excision and Erasion; N. P. Dandridge, Cincinnati; Report of a Porro Operation, and The more frequent use of Chloroform in Obstetrics; J. F. Baldwin, Columbus; The Rôle of the Microbe; A. R. Smart, Toledo; Common Mistakes in Medical Practice; H M. Brown, Hillsboro; Do we take Cold? H. D. Hinkley, Oxford; Puerperal Fever; G. H. Colvill, Harrisville; The Treatment of Compound, Comminuted Fracture; S. L. McCurdy, Dennison; Phlyctenular Keratitis; C. W. Tangeman, Cincinnati; The Epidemics of Diphtheria, Scarlet Fever and La Grippe, at O. S. and S. O. Home; C. M. Galloway, Xenia; Acne: its Nature and Treatment; W. T. Corlett, Cleveland; The Influenza, as seen in the Country; W. W. Pennell, Fredericktown; Indications for Internal Urethrotomy; B. Merrill Rickets, Cincinnati; The Treatment of Scalds and Burns; A. H. Brundage, Xenia; Cough; its Relation to Intra-Nasal Disease; A. B. Thrasher, Cincinnati; A Case of Hematoma of the Ovary, following Chronic Catarrhal Salpingitis, with Operation and Recovery; R. Harvey Reed, Mansfield; Exact Dosage

in Electricity; E. F. Wilson, Columbus; A Case of Labor at Full Term, complicated by Placenta Previa; R. B. McCall, Georgetown.

The announcement of the meeting has been sent to many physicians in the State who are not members of the State Society, but who are cordially invited to attend the sessions of the Society and to become members this year, in order that they may give the Society the benefit of their professional experience and receive the benefit of the experience of other members.

From the titles of papers to be presented, it will be seen that the meeting promises to be both interesting and profitable. Further information may be obtained from the Secretary, Dr. G. A. Collamore, Toledo, Ohio.

Recovery after a Week of Total Anuria.

At the meeting of the Medical Society of the Paris Hospitals on the 14th ult., M. Féréol related a case of a man who, having inherited gout, had on two occasions, within the past two months, had attacks of suppression of urine lasting twenty-four hours, preceded by lumbar pains and hematuria, and followed by the emission of clear non-albuminous urine and a small calculus. A third attack had lasted for eight days, and during that week he only passed a few drops of urine. Then the anuria ceased abruptly, and within twenty-four hours he passed over ten quarts of watery urine containing 1.4 per cent. of urea, or six ounces in the twenty-four hours. At the same time he passed a uric acid calculus the size of a pea and several smaller ones. During the week of anuria he had only slight pain in the right side, and the bladder was empty. But there had been evidence of uremia, as during the last two days there was slowing of pulse to 52, lowering of temperature (37° C.) in the rectum, mydriasis, and a "subjective sensation of an ammoniacal odor in the urine." The treatment consisted in dry cupping to the loins, electrical applications night and morning, inhalations of fifteen quarts of oxygen daily, one quart and a half of milk, half a quart of Vichy water, and half a quart of an alkaline water and Beaujon's diuretic potion, on the sixth day a bath lasting fifteen minutes, on the seventh day a purgative, and on the morning of the eighth day five grains of caffein. M. Féréol did not think that the suppression was due to there being only one functionally active kidney, but rather that the passage and impaction of the calculus had caused a reflex inhibition of the secretion from the uninvolved organ. The quantity of urine afterwards evacuated was opposed to the first-named hypothesis. Urea must have accumulated in the blood, for the skin was dry and the bowels confined, except for a watery evacuation following the purgative. Sixteen days later the patient was in fair health, save for slight lumbar pain and the daily passage of uric-acid gravel. M. Royet mentioned a case, also a gouty subject, eighty years old, in whom a large number of calculi lodged in the ureter without uremia or anuria; when the calculi were passed he had successive attacks of anuria, none of which exceeded thirty-six hours. M. Hayem thought the case was opposed to the generally accepted view that an adult secretes in three days enough urinary poison to kill him. Roberts has said that myosis is characteristic of uremia from suppression, not mydriasis, as in M. Féréol's case if the amount of potash had been estimated in the urine following the anuria, it would have been possible to test the opinion of Voit, Feltz, and Ritter, who say that the toxic quality of urine is proportionate to the richness in potash salts. M. Hayem had always found a large amount of urea excreted after anuria even of short duration.—*Lancet*, March 1, 1890.

Chemical Vaccination against Yellow Fever.

Drs. Castaneda and Borda, of Bogota, with the sanction of the Minister of Public Instruction in Colombia, have been engaged in some experiments upon animals, with the object of discovering whether it is possible, by the injection under the skin of urine from yellow fever patients, which presumably contains some chemical substance due to the action of a specific microbe, to afford protection against the infection of yellow fever. They were led to this research from some experiments upon the "pyocyanic disease" by MM. Charrin and Ruffer, which were communicated to the Paris Biological Society in the early part of 1889, and which showed that the bacillus pyocyaneus, when introduced into the system of rabbits, causes the formation of substances which possess the property of producing the same physiological effects as the bacillus itself, and that

these bodies can be detected in the urine; and also in view of a paper by Dr. Carmona, of Mexico, upon yellow fever. Observations were made with yellow fever urine, both sterilized and non-sterilized, and an approximate idea was thus formed of the dose which ought to be safe for a human being. An opportunity for experimenting on a human subject was not long in presenting itself. A young medical man who was about to settle in practice in Cúcuta—a place which, it seems, has a very evil reputation as a perfect hot-bed of yellow fever—requested that an attempt might be made to afford him protection by means of "chemical vaccination." Accordingly, one-third of a minim of sterilized urine from a yellow fever patient dissolved in sixteen minims of distilled water was injected into his deltoid; this was followed by thirst, insomnia, headache, conjunctival redness, dilatation of the pupils, pain in the arm and subsequently in the legs, some erythema about the puncture, but by no rise of temperature. On the third day the symptoms had all disappeared. A second inoculation was performed with three-quarters of a minim of the sterilized urine in eight minims of diluted alcohol, the thigh being selected for the seat of puncture. This was followed by a marked rigor, pain in the head and limbs, fever, thirst and delirium, with jaundice of the skin and conjunctivæ and albuminuria. In three days all had passed off. Whether the adventurous physician will find that his "vaccination" renders him proof against yellow fever remains to be seen.—*Lancet*, March 1, 1890.

Pancreatic Hemorrhage.

An uncommon cause of sudden death has recently been recorded by Dr. F. A. Harris, of Boston. A working woman, thirty-five years old, was found on a doorstep, complaining that she felt very ill; a few hours before she had been at an "employment office," seeking work. The patrolman detecting a smell of alcohol in her breath seems to have considered that she was intoxicated, and had her removed from the doorstep to the station in a patrol wagon. On arrival she was found to be dead. A *post-mortem* examination was made; the body was well nourished, the brain and membranes, the heart, the great vessels and all the organs, with the exception of the pancreas and lungs, were healthy. The right lung was œdematous and there were some extravasations into the periphery of the lower lobes of both lungs. There was hemorrhage into the splenic end of the pancreas; the whole of this third of the organ being infiltrated with blood, which was easily expressed on section. There was also a small amount of blood effused into the subperitoneal tissue, extending nearly to the supra-renal capsule. The whole amount of blood was apparently not more than a drachm and a half, by estimate. In gross, the pancreas presented otherwise nothing unusual. It was not enlarged, nor were there any gross appearances of fatty degeneration or abscess or embolic infarction. — *British Medical Journal*, March 8, 1890.

Oil of Birch and Oil of Wintergreen.

The *American Druggist*, March, 1890, says that oil of birch and oil of wintergreen were reported in August, 1889, by Messrs. Trimble and Schroeter to be physically and chemically identical, both consisting mainly of methyl salicylate with the addition of a hydrocarbon having a formula $C_{15}H_{24}$, together with small quantities of benzoic acid and ethyl alcohol. They also stated that a sample of artificial wintergreen oil examined by them contained the properties neither of the natural oil nor of methyl salicylate. In reply to this, Dr. Power reports the examination of a number of samples, showing that natural wintergreen oil consists of methyl salicylate and 0.3 per cent. or less of lævogyrate terpene; that oil of birch, when pure, consists simply of methyl salicylate, and is inactive towards polarized light; and that neither contains benzoic acid nor, so far as he has been able to satisfy himself, any ethylic alcohol. In the January number of the *Am. Jour. of Pharm.*, Messrs. Trimble and Schroeter defend their position and combat some of these statements.

Death after Administration of Chloroform.

A traveler, Caleb Henry Jones, while undergoing an operation for some skin disease at Swansea, died suddenly during the administration of a mixture of alcoholic chloroform and ether.—*Lancet*, April 5, 1890.

NEWS.

—Typhus fever is reported to be epidemic in San Luis Potosi, Mexico.

—The American Surgical Association held its annual session in Washington, D. C., last week.

—The Association of American Physicians held its fifth annual session in Washington, D. C., last week.

—The Treasurer of the Rush Monument Committee reports that so far the sum of $1,325.19 has been raised.

—Dr. Edward C. Fletcher, of Plymouth, Penna., died May 13, of consumption, at the age of forty-seven years.

—The bill to regulate medical practice in Maryland, which passed the Legislature, has been vetoed by the Governor.

—The Department of Health in Chicago has been notified of two pronounced cases of leprosy in the Chinese colony in that city.

—According to the *Maryland Medical Journal*, St. Louis is to have a new medical school, called the Marion-Sims Medical College.

—The North Carolina State Medical Society will hold its thirty-seventh annual meeting at Oxford, N. C., May 27, 28 and 29, 1890.

—Five milk dealers, a restaurant keeper and a grocer were held recently to answer at court the charge of exposing for sale and dealing in impure and adulterated milk.

—The one hundred and twenty-fourth annual meeting of the Medical Society of New Jersey will be held at the Health House, Schooley's Mountain, N. J., June 10 and 11, 1890.

—At the meeting of the Medical Society of the State of California, held in Los Angeles in April, it was determined to invite the American Medical Association to meet next year in San Francisco.

—Dr. A. C. Hawley, of Eaton, Ohio, shot himself in his office, May 11. A letter beside him said that he had taken a quantity of morphine. Dr. Hawley was about thirty-two years old, and was graduated from the Miami Medical College in 1887.

—Dr. Walter A. Reid, a "magnetic" physician, was sentenced May 16, in the United States Court at Grand Rapids, Michigan, to one year's imprisonment in the House of Correction. He was convicted of using the mails for fraudulent purposes.

—A Dental Outpatients' Department in connection with the University of Vienna was opened April 21. The new institution is under the direction of Dr. Julius Scheff, and is the first step towards the establishment of a fully-equipped school of dentistry in the Austrian capital.

—The following changes have been made in the Faculty of the Medico-Chirurgical College: Dr. J. M. Anders has been transferred from Diseases of Children to Clinical Medicine; Dr. Ernest La Place has been made Professor of Pathology and Clinical Surgery; Dr. Samuel Wolfe has been made Professor of Physiology.

—The German Minister, Count Arco-Valley, announces to the Medical Press that he has written to Berlin to have the time for the reception of entries for the International Medical Exposition, in connection with the Medical Congress, extended so that those coming from the United States may be received after May 15.

—Dr. Antonio Parchini-Bonfanti, Director of the Rossi Casa di Salute at Milan, died recently. He gave much attention to hypnotism at a time when such studies were held in great contempt, and published an interesting work on the subject. He was offered the Chair of Forensic Medicine in the University of Pavia, but declined the honor.

The next State Legislature of Illinois will probably provide for an additional asylum for the insane, and the homœopathists propose to try to have it put in charge of their school of medicine. To this end they will unite in an effort to secure the nomination of general State officers and members of the Legislature pledged to give them what they want.

—The Detroit *Journal* is authority for the statement that a portion of the lungs of President Garfield were taken at the time of the autopsy and cut up and distributed among microscopists. Upon being interviewed as to the foundation for the statements, the *Journal* states that it knows of persons in Detroit who have such portions in their possession.

—Local committees of women in all the large Eastern cities are actively engaged in endeavoring to secure contributions of money for the purpose of founding a medical school in connection with the Johns Hopkins University, of Baltimore, Md., at which women may study medicine as well as the men. It is expected that all the committees will turn in at least $100,000 by June 1.

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

GLYCOZONE

Is used as an internal remedy, or for local dressings. It is absolutely harmless; and Ozone is its healing agent.

GLYCOZONE, by its wonderful antiseptic and healing properties, not only prevents the fermentation of the food in the stomach, but it quickly cures the inflammation or irritation of the mucous membrane. It is a specific for disorders of the stomach: **Dyspepsia, Catarrh of the Stomach, or Gastritis, Ulcer of the Stomach, Heart-Burn.** Sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing CHAS. MARCHAND'S label and signature.

Prepared only by Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

A book containing full explanations concerning the therapeutical applications of GLYCOZONE, with opinions of the profession, will be mailed to physicians free of charge on application.

GLYCOZONE	¼ lb. bottle, retail price,	$1.00
	½ lb. " "	1.75
	1 lb. " "	3.00

SOLD BY LEADING DRUGGISTS.

Laboratory, 10 West Fourth Street, New York.

RICKETS.—CRUSHED FOOT.—OSTEOMYELITIS.—ABSCESS OF THE BACK.—OSTEOMYELITIS.

BY ROSWELL PARK, M. D.,

PROFESSOR OF SURGERY AND CLINICAL SURGERY, UNIVERSITY OF BUFFALO.

Rickets.

I want you to notice how this child walks, the contour of his abdomen and the size of his head. See how much like a miniature alderman he looks, with his protuberant abdomen. The top of his head is nearly flat and his legs are widely bowed apart, not from distortion at the knee, but from curvation of the shafts of the tibiæ. In addition to the curvation, there is a spiral twist of the tibiæ. The peculiar overhanging belly made me think of congenital dislocation of the hips, but there is no such trouble; although there is some change in the shape of the femurs, and I think the neck of the bone is peculiarly implanted.

This is a well-marked case of rickets. You can see much more notable deformities than this in certain cases, but this is a fair sample of what you will see a great deal of in this country, notwithstanding the fact that books on the subject generally speak of America as a land of freedom from rickets, as from other evils.

By making long-continued pressure in the proper directions, the probability is that this child's legs may be made to grow straight. It is almost impracticable to make forcible pressure without causing ulceration; by making mild pressure for a long time we can avoid this. If a speedy result is desired, we might anæsthetize the child and bend the legs forcibly, and then put them up in plaster of Paris. In still worse cases we use the bloody method, cutting down on the bone, making a nick in it and breaking it at that point, or, in very bad cases, re-

moving a wedge-shaped piece of bone with the chisel, and closing up the gap. This really consists in producing a compound fracture; but we do it under the most favorable circumstances, the wound being aseptic and the fracture at the most desirable location, and the dressing is applied immediately. The operation does not make an absolutely straight bone; but it is approximately so. During the winter I shall probably have occasion to operate on cases of knock-knee, and I can then say more about this bloody method.

Crushed Foot.

This young man has had his foot crushed under an engine wheel. Not much is to be seen except a very much discolored and ecchymotic leg and an abrasion of the skin over the internal malleolus and behind and below the external malleolus there is a black patch of gangrenous skin which will slough off, leaving a raw surface which will heal by granulation and be covered by epithelium. The ecchymosis is due to blood escaping from the lacerated subcutaneous vessels and working its way slowly up under the cellular tissue beneath the skin. It does slowly what emphysema accomplishes rapidly, the process having already occupied six days. The fluid part of the blood is absorbed and the coloring matter remains for quite a time and, as the blood ages, it goes through certain well-marked changes in color.

When this man entered the hospital the heel could be moved on the foot, and there was crepitus, indicating fracture of the os calcis, which is pretty rare. There is no deformity in such a case, and the detection of the fracture requires some ingenuity. Fractures may, and undoubtedly do, occur in the tarsal bones without being recognized and being diagnosticated as bad sprains.

In this case the foot was dressed with a piece of clean blanket dipped in a hot hydronaphthol solution; for I have known pyemia to occur after a little subcutaneous bruising of this sort. Hot fomentations are no longer needed here, but I will continue the use of moist antiseptic compresses, and after the swelling has gone down a little more, and the man feels like moving his foot, I will put on a roller bandage snugly, and no splint will be used unless for the sake of protecting the foot after he gets up. He will probably recover the complete use of his foot.

Osteomyelitis.

Last spring this boy had high fever, delirium, swelling of the leg and other symptoms of acute infectious osteomyelitis or periostitis. As a result there was necrosis so that I had to remove almost the whole shaft of the bone from one epiphysis to the other. Since then it has healed up very nicely, nearly all the bone having been reproduced from the periosteum, but at two little spots the disease continues and there are sinuses discharging pus. As in malignant diseases there is a tendency of these tuberculous bone diseases to return, and I am never surprised, although I am sometimes a little chagrined, to have to operate a second time on a case of this sort. It is an experience which every surgeon has. The sharp spoon goes into quite a little cavity, which I will scrape out. I will pack the cavities with zinc oxide gauze and apply an outer dressing of dry zinc oxide gauze and bichloride cotton.

Abscess of the Back.

Here is a young Slav. About three weeks ago he was lifting something heavy, and strained his back. He now has a swelling on the back which is painful and fluctuating, and over which the skin is reddened. It is, undoubtedly, an abscess, probably due to tearing some fibres of fascia or possibly muscle, or to laceration of connective tissue. It is barely possible that this might be an empyema which is pointing through between the ribs. I remember once being called to see a lady who was thought to have cancer of the breast, but the case proved to be an empyema which had opened behind the breast and was pushing the breast forward. If this were empyema, I would expect the physical signs, such as coughing, etc., which are not present here. There is good resonance all about the tumor.

This swelling might be due to a perinephritic abscess; but it has come on too rapidly.

I shall open the abscess at the place which shall be most dependent when the patient sits up. [About 600 c.c. of creamy pus was removed, and the cavity was irrigated with a 1–3000 mercuric chloride solution.] I can now push my finger underneath the skin in all directions. I will resort here to overdistention, which washes the cavity out well and stimulates healing, and will then insert a drainage-tube, fixing it with safety-pins to

prevent its slipping into the cavity. I once saw a drainage-tube lost in the pleural cavity through omitting this simple precaution.

Osteomyelitis.

The next patient is a man twenty-two years old. When a boy, he fell while playing base-ball and hurt his knee. As a result, there was local pain, tenderness and swelling, and he was confined to bed for ten weeks. Disease of the lower part of the right femur has followed. It is, undoubtedly, another case of suppurative disease in bone with more or less local destruction of tissue, coming on after the manner of an acute osteomyelitis or periostitis or, more probably, a combination of both. You see a sinus in the lower part of the thigh which is discharging pus. When the sinus closes, he begins to have severe pain with redness of the overlying tissues, then it bursts out and he is free from pain and has the discharge for awhile; and so for years he has alternated between retention of the pus and spontaneous evacuation and relief. Little pieces of bone have been discharged, making it, beyond the possibility of doubt, a case in which the bone itself is involved; but whether it is caries or necrosis, I cannot yet say. I think it is a combination of both.

The sinus was opened and curetted, firm bands of cicatricial tissue making this difficult. After removing the diseased bone the sinus was packed with zinc oxide gauze, and an antiseptic dressing was applied.

COMMUNICATIONS.

THERAPEUTICS OF COLD.[1]

BY S. N. WILEY, M. D.,
NORRISTOWN, PA.

When we consider the fact that almost all diseases that we, as physicians, are called upon to treat originate in inflammation or are more or less affected by it during their progress, it becomes at once evident that any means that will prevent, modify or obliterate an inflammation, in any or all of its stages, is a great power in the physician's hands.

[1] Read before the Montgomery County Medical Society, March 5, 1890.

The great surgeon, Gross, has said that "the smallest pimple on the nose is as much an inflammation as an erysipelas that covers the face and head. An ulcer of one of the mucous follicles of the mouth does not differ, in principle, from an ulcer of one of the glands of Peyer, which are the seat of so much disease and danger in typhoid fever."

Many diseases vaguely called nervous, are nothing but forms of inflammation, the nature and seat of which it is often difficult, if not impossible, to determine. Their predominant symptoms are of a nervous character, and hence the diseases which they accompany are usually considered as nervous, while in reality the contrary is too frequently the case.

In all diseases attended with an inflammation there is a local or starting point from which the morbid process extends. This is true whether the disease be a local or a general one, whether it has its origin from within or from without.

In all acute inflammations, whatever their cause or situation, active congestion is a necessary antecedent of the morbid action, one of the first links in the chain of the malady. Hence it may be regarded as a part or parcel of the inflammatory process ushering in the disease and continuing up to the very point of effusion—in other words, ceasing only where effusion commences.

But active congestion is not always necessarily followed by inflammation, although prone to pass into that state if it continues even for a short time. The cause which induced it having been removed, the vessels cease to attract blood in undue quantities, and, getting rid of the surplus, they speedily regain their normal caliber and function.

The most prominent external symptoms of inflammation were tersely stated by an ancient writer as "rubor, calor, cum tumore et dolore." The immediate cause of the change of color in inflammation is a preternatural afflux of blood.

With discoloration, heat is one of the most common and constant effects of congestion and inflammation, and hence a valuable symptom of the disease. It is well known that the extremities—the hands, feet and ears—are habitually cooler than the trunk, or portions near the trunk, because they have naturally a more feeble circulation; hence, in inflammation, although their temperature may not reach 98.4° F., yet, if there be any elevation of heat over and above what these parts show in a

healthy state, it is to be considered an actual augmentation.

Swelling is seldom entirely absent in inflammation of the external parts of the body, although it may be in that of certain internal structures. The immediate cause of swelling is twofold: first, engorgement of the vessels of the part, and secondly, and mainly, effusion of serum and fibrin.

Pain is one of the most constant symptoms of congestion and inflammation, usually setting in early and steadily, increasing in severity until the morbid action has attained its maximum.

As a general rule, the pain is greatest at the focus of the inflammation; it is usually fixed in its situation, but sometimes it darts about in different directions. It is increased by motion, by pressure, and by posture. Pain is sometimes felt at a point more or less remote from the seat of morbid action, and therefore does not always serve to denote its existence.

But pain is not always present even though the inflammation be extremely violent. This is well shown in typhoid fever, attended as it is with inflammation of Peyer's glands, often terminating in extensive ulceration, and yet the patient complains of little or no pain from first to last.

Now how is pain produced? Many theories have been advanced, but the most plausible opinion is that pain is caused by the compression of the nerves of the part by the distended vessels and the effused matter, thereby impeding or interrupting the transmission of nervous fluid and causing it to accumulate or explode at the point of obstruction. Of course the various component structures of the nerves themselves are also inflamed.

We know then that the most prominent and constant symptoms of external inflammation are discoloration, swelling, heat and pain. Now what occurs in the external parts of the body immediately under the eye of the observer may be supposed to happen under similar circumstances in the internal viscera. Thus we know that when there is a sudden repulsion of the cutaneous perspiration the blood is extremely apt to collect in the lungs, causing active congestion of the pulmonary tissues, which unless speedily relieved will end in a more or less disastrous pneumonia.

Now as all inflammation, in whatever part of the economy, is attended with heat, swelling, discoloration and pain, and as these symptoms all depend to a greater or less extent upon the superabundance of blood in the part, it follows that, if inflammatory diseases were recognized in their early stages, and we had an ideal remedy which would allay the congestion and early inflammation, allay the heat, pain and swelling, we should be able to arrest the disease in its very infancy; to cut it short, and thereby save our patients much suffering, much loss of valuable time and often to save life itself.

A specific or a universal remedy for this purpose has to the best of my knowledge, not yet been found; but the remedy which in my observation and experience comes the nearest to fulfilling all the requirements under most circumstances is *cold*, applied either by means of ice or by means of ice water. Cold has been employed in the treatment of inflammation almost from time immemorial; but like many other good things it has at times been forgotten or laid aside for newer remedies. Medical history informs us that there was a period, about the end of the last and the beginning of the present century, when cold was almost unknown as a therapeutic measure.

Within my own recollection, to apply cold externally or to give a patient suffering from a high fever ice to eat or cold drinks was to fly directly in the face of public opinion. It is not difficult for one to conceive how cold operates in subduing morbid action. Its chief effect is evidently that of a sedative, lowering the temperature of the part and causing contraction of the vessels, thereby relieving pain, swelling and tension.

It is particularly applicable to inflammation in its incipient stages, where there are, as yet, little effusion and no structural lesion. When the action has reached its acme, threatening suppuration, or a tendency to gangrene, it is usually hurtful, both to part and system, and should be promptly discontinued. Cold may be applied in several different ways: the cold bath, the graduated bath, cold effusions, the cold pack, cold sponging, cold compresses and frictions with ice.

There is little or no reason for believing that the application of cold in any of its forms has power to modify the conditions upon which the production of heat depends; but there can be no doubt that under its use distressing and dangerous symptoms are often much relieved and the whole morbid process arrested.

In general fevers of great violence the systematic application of cold by means of baths or the wet-pack is capable in many cases of rendering important service. The temperature of the bath should range from 65° to 80°; its duration should not exceed ten minutes. The patient, when removed to the bed, should be wrapped in a sheet without drying, and should be comfortably covered. The greatest objection to the general bath in private practice is the fact that it is seldom convenient to have a bath brought to the bedside of the patient; and in a serious illness it causes too much disturbance and movement to take the patient to the bath. For children a common wash-tub answers every purpose and is found in every house.

When the wet-pack is employed, two beds should be used side by side. The body and thighs of the patient should be wrapped in a sheet wrung out of cold water, and allowed to remain in the pack ten or twenty minutes. As the sheet becomes heated the patient should be placed in a fresh one on the second bed; and the transfers should be continued until the desired fall of temperature is effected. Usually about four packs will be found to equal one bath.

In general fevers, cold sponging and frictions with ice are the most convenient and at the same time most agreeable and effective modes of reducing heat.

I should exhaust your time and patience were I to recount the various forms of applying cold to the body in all the many forms of fevers, as I have used it—for I am giving you my personal experiences. Suffice it to say, that I have found it the safest, the most constant in its effects, the most agreeable to the patient, as well as applicable to the greatest number of cases of any or all antipyretics.

Did time permit, it might be interesting to refer to the use of ice and cold water, internally and externally, in cases of typhoid fever, scarlet fever, puerperal fever, cerebro-spinal fever; in cases of acute gastritis; in ulcer of the stomach; in hemorrhage from the bowels; in hemorrhoids; in diphtheria; in acute laryngitis, pharangitis, and tonsillitis; and in croup—all of which are attended with more or less severe inflammation, and in all of which I have found the use of ice and cold water not only very grateful to the sufferer, but of the highest value. Its use is also invaluable in inflammatory affections of the membranes of the brain and spinal cord, in concussion of the brain, and in thermic fever.

In the convulsions of children, cold applied freely to the head, either by means of ice-water poured on, or by means of bladders of ice, will be found the safest, the most prompt, and efficient means in breaking up the convulsions; and the continued use of the cold will prevent their return until the cause of the trouble can be removed.

In the foregoing maladies experience has taught me that, notwithstanding the teachings of the books to the contrary, cold may be applied, in the form of bladders of ice, continuously for many days in succession, without doing any harm whatever. The ice-bag must not, however, be laid on the part and allowed to remain. I invariably direct an attendant to sit by the patient and to devote his or her whole time and attention to the frequent change of the location of the ice-bag. And just to the degree in which my directions are carried out, do I get good or bad results.

In headaches, and in all conditions in which the head is hot and the face flushed, applications of ice will be found most beneficial. In severe cramps of the stomach and bowels, the pouring of cold water from a pitcher, held three or four feet above the patient as he lies on the floor, acts like magic in allaying all the symptoms.

How often do we see a patient at our first visit suffering from pain in a part or an organ, possibly without any general fever, and with no other symptoms; and, instead of searching carefully and intelligently for the cause of the pain or distress, prescribe an anodyne, to go our way, only to find on the morrow that our patient has had a chill, and is suffering from a high fever, that a local congestion has passed into inflammation, and that he is now in the clutches of some formidable disease, whose beginning had a slight cause. Had the early condition been recognized, and the proper remedies for congestion and beginning inflammation been applied, we might have saved for him time, distress and possibly his life.

In local inflammations from whatever cause my main reliance is upon the use of ice or ice-cold water. In applying ice I find the best results from its use in a hog's bladder, rather than in the rubber ice-bags sold for the purpose. In glandular swellings, in boils, in abscesses and carbuncles, when seen, as they often are, in the early

inflammatory stages, before suppuration has taken place, I invariably direct the use of ice, and I am scarcely ever disappointed. A large piece of ice is procured and placed dry in a basin or other vessel by the side of the patient. Two compresses, large enough to cover the inflamed part, are wrung out of water and placed upon the ice. As soon as it is cold one is laid upon the part, and while it is there the other is on the ice; the transfers are made at frequent intervals until the desired end is attained. Here, as in most cases, the bladder of ice will be found convenient and unobjectionable.

Under its use the heat, the pain and all the symptoms will quickly subside, and in a few hours what promised to be a dreaded affection has been entirely obliterated, and the parts resume their normal appearance and function.

I have seen in my own practice, in eleven years, only two cases of mammitis, or gathered breast; and both of these were the direct result of disobedience of my orders upon the part of the nurse. And yet during that time I have seen a large number of cases in which the mammary gland was involved in the inflammatory action; when the organ was exceedingly large, hard, heavy and lumpy, exquisitely painful, and intolerant both of manipulation and pressure; with the skin hot, discolored, tense and glossy; with the secretion of milk entirely arrested or much diminished; with the ducts almost entirely choked up; the patient herself exhibiting well-marked constitutional symptoms.

If permitted to proceed, every one knows that suppuration will inevitably follow, entailing a great amount of suffering and distress upon the mother, the present and possibly the future loss of the gland's usefulness, and a great deal of annoyance to the physician. Under such circumstances what is to be done? Apply a bladder of ice, and in a very short time all the symptoms, both local and constitutional, disappear. Then with gentle rubbing and the application of a suitable pump, the organ is soon in its natural condition, with its present and future usefulness saved.

In acute inflammations of the joints, ice is the most valuable of all applications. I am very frequently met with expressions of surprise and often with opposition where the use of ice and cold water are suggested, either in general fevers or in local inflammations—this in families where I have occasion to use it for the first time.

In all cases where ice and cold water have already been judiciously used, I find the patient and his friends not only ready but anxious for their use under similar circumstances. I am very frequently told by my patients of local inflammations which they have broken up, of diseases they have intercepted or prevented by means of ice and cold water; and in nearly all families where I have ever treated a case of convulsions of children, when like trouble comes, I find them on my arrival pouring cold water on the little sufferer's head.

New antipyretics are constantly being brought to our notice, through circular letters from the manufacturers, through the advertising pages of our journals, through personal appeals from agents, and in articles written by physicians too evidently in the employ of the manufacturer—some of which seem to be very good—some of which certainly are unreliable. But as long as the human system remains as it is, and the winters continue to be cold enough to produce ice, I want no better remedies in the majority of cases, than those which nature so strongly indicates—ice and cold water.

TREATMENT OF SUPPURATION OF THE MIDDLE EAR.

BY L. J. HAMMOND, M. D.,

ASSISTANT SURGEON TO THE EAR DISPENSARY, UNIVERSITY OF PENNSYLVANIA, PHYSICIAN TO THE PHILADELPHIA DISPENSARY.

The majority of acute inflammations of the middle ear are seen first by the general practitioner. Especially is this so in country practice. Occurring, as they do, from exanthematous diseases, colds and teething, it is he who can be of the greatest service in preventing permanent impairment of hearing, which is most likely to occur if such diseases are neglected at this stage; while their dangers will be largely averted if they are properly treated. With these facts before us, a few suggestions as to how diseases of the ear can best be treated by those who have not had the advantages of a clinical experience may be of service.

The first symptom of inflammation of the middle ear is pain, which should be relieved by blood letting, with leeches (Swedish), two to four in number, applied over the tra-

gus, or by the use of the artificial leech over the same region. Should it be desired to withdraw more blood, the flow can be kept up by the use of hot flaxseed poultices, applied over the parts. In infants and in very old persons it is best to rely entirely on moist heat, which can be applied by wringing flannel out of boiling water and applying it over the ear, or by the use of flaxseed poultices, which should be made large and thick and placed over the ear as hot as can be borne, care being taken to place a cotton pad behind the auricle in order to prevent its being pressed backward, which would greatly increase the pain. Over the poultice should be placed oiled silk—or, in its absence, paper—and a bandage or handkerchief to hold it in position. The poultice should be replaced by a hot one as often as it cools, and this should be continued until all acute pain subsides. At this stage the inflammation may subside. If it does, the use of moist heat should be discontinued, and dry heat may then be used. This is best accomplished by applying large pads of absorbent cotton over the ear and continuing their use until all tenderness over the tragus or mastoid regions subside.

In the majority of cases of this sort the inflammation goes on to a higher stage, namely, that of pus formation. Then the membrane ruptures spontaneously, if it is not opened by paracentesis; and a free discharge of pus follows. The acute pain at this stage usually subsides. Here, as in the above condition, the use of moist heat should be discontinued and cotton pads should be substituted. In addition to this the canal should be thoroughly cleansed, either by the use of an ear syringe and warm water; or, in its absence, the same result can be accomplished by the use of a sponge shaved to a point at one end. The head should be placed in a horizontal position and warm water allowed to flow from the sponge into the canal, which can be dried by inserting the pointed end of the syringe or of the sponge in the canal. The canal should be straightened during the cleansing by drawing the auricle outward and slightly backward. The patient should several times during the cleansing of the canal inflate the ear by the Valsalva's method, which consists in closing the mouth, holding the nostrils with the fingers and by a forced expiratory effort forcing air through the Eustachian tube into the middle ear cavity. In this way the pus which remains in the middle ear cavity is forced through the perforated membrane into the external canal and may be removed during the cleansing. After thorough cleansing, a cotton plug, 1¼ inches in length if the patient be an adult, and 1 inch long if a child, can be made by loosely twisting absorbent cotton round a match of proper size for the canal. The plug may be inserted into the auditory canal and it will act as a protector from the air and as a drain, and should be removed as often as it becomes saturated with pus. After each cleansing, which should be done once daily, the cotton pad should be again applied. This method of treatment should be continued until all tenderness over the regions described has subsided, after which time insufflations of finely powdered boric acid, or—what I much prefer—equal parts of iodoform and boric acid, should be blown into the canal, either through an instrument made for the purpose (an insufflator), or, in in its absence, through a quill of sufficient size to fit the canal.

As inflammations of the middle ear are generally the result of an extension of inflammation from the naso-pharynx, treatment of these surfaces should be instituted from the onset of the attack. The nose and throat should be thoroughly cleansed with an alkaline solution such as Dobell's solution, or:

℞ Listerine . . . . . f℥i
Glycerini . . . . . f℥iii
Sodii bicarb.
Sodii biborat. . . . . āā ℥jss
Aquæ q. s. ad. . . . . f℥iv

M. Sig. f℥i in f℥ii warm water snuffed up the nose, and as a gargle for the throat three times daily.

The latter I have found very useful in removing the muco-purulent discharge from the naso-pharynx. If in a child, it can be used by injecting it through the nasal canthus with a sponge. After thorough cleansing with the solution, the throat should be gargled with some good astringent, such as:

℞ Acid. tannici . . . . . ℥iii
Pulv. aluminis . . . . . ℥ii
R[illegible] chloratis . . . . . ℥i
Glycerini . . . . . f℥i
Aquæ q. s. . . . . ad. f℥iii

M. Sig. f℥i in f℥ii warm water as a gargle, t.d.

If the patient be a small child, small quantities of chlorate of potash, mixed with sugar, can be placed in the mouth and allowed to dissolve. The patient's general condition is usually below par, and this state

should be met with stimulants and tonics, such as milk punch, beef tea, tr. ferri chloridi and cod-liver oil. The patient at the same time should be kept in the house, and if possible in bed.

IMPROVEMENT IN TELEPHONE PROBE.

BY HARVEY B. BASHORE, M. D.,

WEST FAIRVIEW, PA.

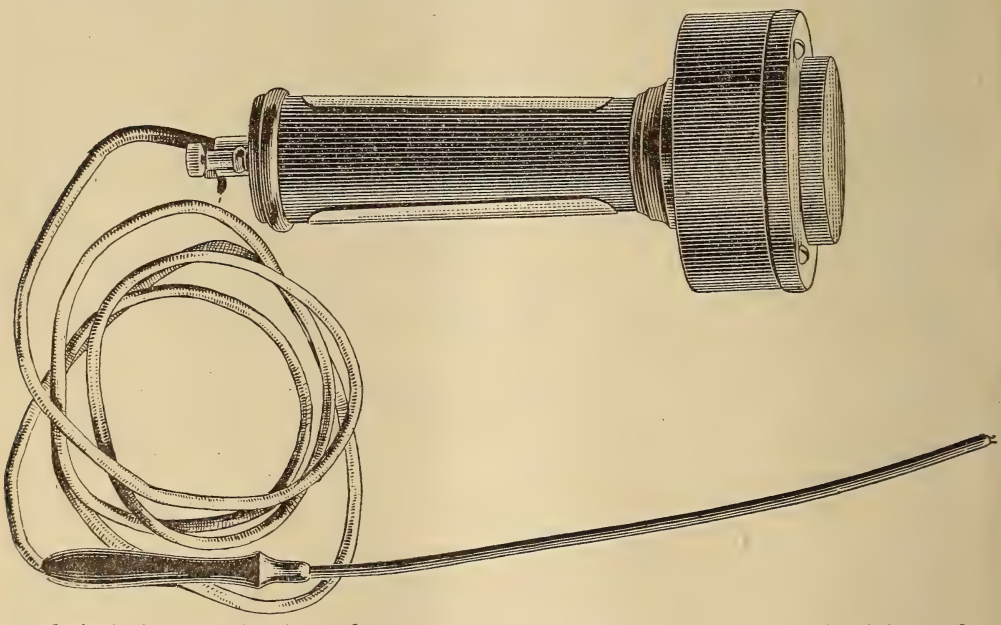
In the REPORTER, September 28, 1889, I described the Telephone probe, as consisting of a telephone, a probe and a battery.

I again wish to speak of this instrument, because of certain improvements I have made in in it, rendering it much more practical and useful. The battery, as such, is dispensed with; and the instrument, as I have now made it, consists of a telephone and a probe proper. To the handle of the telephone are fastened, at opposite points, a zinc and copper plate. The zinc plate is connected with one end of the coil; the copper plate with one binding post, and the remaining end of the coil with the other binding post.

All these connections have been made in the handle of the telephone, and only the two plates are visible. By grasping the handle of the telephone with the hand a current is generated, due to the contact of two dissimilar metals. This is made apparent, if the circuit be closed, by a clicking sound in the instrument; and this sound is heard whenever a current is "made" or "broken" between two good conductors, that is, the metals and carbon. The probe consists of a flexible canula, containing two insulated wires, the tips of which project a short distance beyond the canula. The flexibility of the probe is, I think, a distinct feature.

If, now, the handle of the instrument be grasped, and the projecting tips of the probe come in contact with a metal, such as a bullet in the tissues of the body, a metallic contact is made; and the indication is given in the telephone.

Of all electrical probes, the telephone must be the most reliable and efficient; for the telephone, used as a current indicator, is the most sensitive galvanometer we possess, indicating a current less than .000001 that of a Le Clanché cell. In comparison with any other probe, using the electricity of the body, this must be the most efficient, as giving the least trouble for its arrangement, and indicating the presence of any metal, whether similar to that of the terminals or not.



The instrument thus described has been made for me by Messrs. Leach & Greene, of Boston; and to them I owe thanks for the efficient manner in which they have carried out my ideas.

TYMPANITES FROM OVER-FEEDING.

BY J. E. FREE, M. D.,
BENEZETT, PA.

In M. P. Hatfield's Chautauqua text-book on Physiology mention is made of a rare case, in which a man split his diaphragm and died, in consequence of eating four plates of potato soup, and drinking numerous cups of tea and milk, followed by a large dose of bicarbonate of soda to aid digestion. The gas which would be generated under such circumstances might not be hard to identify, if the chemical constituents of the ingested food are taken into account, together with what is in the stomach before eating. But such knowledge will not avail much if it is not supplemented by sound therapeutics. If a man is obliged to carry his accumulation of flatus around with him until the country doctor can demonstrate to his satisfaction what reagent will, by chemical affinity, cause that wind to disappear, he might drag out a miserable existence for some time.

I have never seen the diaphragm ruptured, but I have frequently attended patients whose voracious appetites have led to the production of gas to an enormous degree. In this section of country many men gain a livelihood by working in the lumber woods, and in order to do the work required, they eat an astonishing quantity of food. Sometimes after an unexpected snowfall, or when a break-up is threatened, they work day and night. At such times they eat as many meals at night as in the day. Loss of sleep, and irregularity of diet, together with neglect of all hygienic measures is the cause for the frequency of what the lumbermen call "cramps."

The case of a man in one of the camps five miles distant will illustrate the subject. He is about forty years of age, is a young married man, is a total abstainer, and during the war was in Andersonville and Libby prisons. He blames his present complaint upon the hardship and exposure of that period; but it seems as if it were possible to do more damage to the body by an over-abundance of food than by its lack.

After a hearty meal at night this patient goes to bed feeling well. Two or three hours later he is awakened by pain in his stomach. This is not severe and comes by spells, which gradually increase in severity and duration until the agony is pitiable to witness. The first time this winter that he had an attack he swallowed all kinds of nostrums without receiving any benefit, and finally sent for a physician, who responded by sending a dozen morphia powders, with the information that he had cholera morbus.

He used the most of these powders without receiving any benefit. Then I was summoned and the patient received two ten-drop doses of chloroform and was up walking about the camp in fifteen minutes. Relief was so quickly accomplished that there appeared to be something not exactly straight about the matter. But the patient insisted that several times when he had obtained the right kind of medicine something seemed to "let go" in his stomach and he was cured. Not wishing to put too much faith in his description, a dose of calomel and ipecac was prepared; but just at this juncture the physician who was first called made his appearance and the case was turned over to him.

Three weeks later, at about two o'clock in the morning, I was again summoned to this man's bedside. He was having a rehearsal of the same performance.

I gave him chloroform and had the satisfaction of seeing him recover in a few minutes. When leaving I told him to be sure to attend to the function of the bowels, and ordered a mercurial purge. He had taken several morphia powders before I saw him this time. Two weeks after this attack he felt another coming on, and aborted it with chloroform, a supply of which he kept on hand.

He now enjoyed perfect health for two weeks more, when the enemy again moved on his works without warning. His first act was to take a purgative; but it did not relieve the trouble, so he sent a message for me, with the statement that he was dying. If he had told the truth, perhaps there would have been a rupture of the diaphragm; but he did not, and that is the closest I have ever come to witnessing this injury. By the time I reached him he had used several doses of the chloroform without benefit, consequently a hyperdomic injection of morphia was administered. A mustard plaster had been applied to the abdomen early in the attack, and now a flannel rag was laid over the region of the pain. It was no sooner put on than it was torn off with a shriek of agony. He said, in explanation, that it felt like a shovelful of hot coals. Inhalation of chloroform was finally resorted to, and relief was

almost magical. But the pain returned, considerably moderated, to be again subdued by the anæsthetic. This was repeated several times until the patient was able to go about his business.

The morphia was a valuable adjunct to the chloroform, although the rôle of the remedies in the disappearance of the tympanitic condition is not as clearly defined as we might wish. Morphia subdues the pain by its stupefying influence upon the nervous system, but would not influence the escape of the gas. I have often seen the pain return as soon as its grasp was relaxed upon the nerve centres.

Tincture of assafœtida, tincture of robina and fluid extract of cascara sagrada, in equal parts, acts nicely in getting rid of gas, by the rectum. A teaspoonful at a dose once relieved a female patient, but set up a temporary, griping diarrhœa, a sort of *similia similibus curantur*. Afterwards ten drops of the "onion medicine," taken daily, completed the cure.

Only once was there any eructation while using chloroform in the case above described. What physiological effect chloroform exerts I do not know. It has been known to relieve this kind of trouble when applied locally, by its counter-irritant property. Again it will accomplish the same end when given by the mouth; perhaps it does so by exciting the same kind of influence as it does upon a carious tooth. When it is inhaled, the relaxation which results is the cause of the relief from pain.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Forty-First Annual Meeting, at Nashville, Tenn., May 20 to 23, 1890.

First Day, May 20.

The meeting opened with about 500 delegates and permanent members in attendance. It was called to order by Dr. W. T. Briggs, who delivered an

Address of Welcome.

He reminded his hearers of the greatness and dignity of the body, which included every quarter of the vast confederacy of States, and was devoted to the most humane calling to which the intellect and energy of man may be devoted, and said that they had not made the great pilgrimage to a common centre for purposes of self-aggrandizement, but to refresh their loyalty to the principles established, and to contribute to the common treasury of scientific facts. Just a third of a century ago—the period of a generation—the Association had honored Nashville by convening there. What changes have taken place in medical science, in the profession, in the personal membership of the Association and in the city that welcomed them. Then the city was an inland town, with not more than 20,000 inhabitants, and none of the marks of a progressive American city. Even then, however, it was refined and classic beyond towns of its size, and had for a long time been a renowned seat for education and learning. It was distinguished as the home of men whose names resounded throughout the nation. Shortly thereafter marching armies had trod it in the mire of devastation, but when the war had passed, its people bent all their energies to build up its waste places, and to build up, also, their loyalty to the General Government from which they had been alienated. The prosperous city stretching in every direction from the crest of Capitol Hill, its suburbs dotted with the chimneys of many factories, its stately universities and colleges, its hospitals and asylums, its libraries and handsome public buildings, its animated streets clanging with the whirl of seventy-five miles of electric railway, traversing its main portions and binding its extensive area, the vigorous movements of its people immersed in the activities of life, all attest how well the work of restoration and advancement is being accomplished. To such a city he voiced the sentiment of its every citizen in welcoming this honored body, and wishing its members to feel that the meeting of 1890 had not only been profitable, but that it was good to have been here, and, when they leave, their hands shall ache from the grasp of the warm right hand of Southern hospitality.

In the absence of Gov. Robert L. Taylor, who had been called to the eastern division of the State on business, Hon. Thomas D. Craighead, State Senator, welcomed the body in behalf of the State.

Hon. C. P. McCarver, Mayor of Nashville, extended the welcome of the city in a humorous and appropriate address.

The programme of the meeting was then announced, and letters were read from some absent members.

THE PRESIDENT, DR. E. M. MOORE, of Rochester, N. Y., was then introduced and delivered his address on

Hygiene in its Relation to the Government.

He said that hygiene does not receive the attention which it deserves in this country. Yet we have no cause to despair, for we are progressing, slowly though it may be, in the right direction. In proof of this assertion he went over, at considerable length, the history of Congressional legislation on sanitary matters since the passage of the first act of that nature in 1796. This act directed the President of the United States to assist the State governments in the execution of the quarantine laws enacted by their respective Legislatures. This was followed at infrequent intervals by other similar laws, their execution, however, being intrusted to the Secretary of the Treasury instead of to the President. This was done because it was this department that was specially affected by the enforcement of quarantine.

In 1878 another advance was made whereby the Surgeon-General of the Marine Hospital Service was empowered to make rules for the Consuls in foreign ports with reference to the condition of vessels and cargoes bound for ports in the United States. During the same year still further advances were made by the appropriation of money to defray the expenses incurred in the investigation of the origin and causes of epidemic diseases, and by the establishing of State boards of health. A natural outcome of State boards was the National Board, the development and growth of which the speaker then traced to the time when it was established, March 3, 1879. The National Board of Health, he said, had a splendid record. Brought into being by the presence of an overwhelming calamity, it achieved a success that was the most remarkable in the history of hygiene, in converting Memphis from a pest-house into a healthy and flourishing city.

The marine hospital service was, he said, the most active and prominent among the functionaries of health under the direct rule of the National Government. One could not become familiar with its work without having a strong feeling of admiration for the care with which the service was administered. The management of the late epidemic of yellow fever was proof of the efficiency and value of this service. There was still another field of sanitary action, that of the consideration of animal diseases. In 1884 a bureau of animal industry was organized for the study of the contagious diseases of cattle and placed under the control of the Commissioner of Agriculture, who had been successful in arresting the spread of pleuro-pneumonia. The best results had been obtained by co-operation with State authorities. The speaker then reviewed the work of this branch of the Government.

The Government had shown willingness to advance in the great work of hygiene, but did not take the initiative. To illustrate this he cited the investigations of Sternberg and Frere and the doings of the International Conference and of the convention of Montgomery.

Taking up the question of regulation, he asked, Could a National Board of Health meet the requirements indicated in the exclusion of epidemics from our borders; their passage from State to State; the hygiene of cars; the drainage of swamps in malarial districts; the adulteration of food and the various other matters which would come within its province? The work would be too great for such a body. The Secretary of the Treasury was now obliged to make regulations through the Marine Hospital Service, which had no natural relation to the object for which the service was created. The service had its laboratories, and the army, navy and Bureau of Animal Industry theirs. These disconnected departments should be consolidated, and the solution of the question, he thought, must be found by the appointment by the Government of a single man who would give his undivided attention to this great subject. That man need not be a medical man, but he should be to his functionaries what the Secretary of War was to his. The control of all the bureaus of investigation should be under one head. The time had come when the health minister should be appointed. When the Government had consolidated these bureaus of investigation and hygiene it would be found that of all the men chosen by our chief magistrate to aid him in carrying on the functions of the Government, the Secretary of Sanitation would have the most arduous labors to perform.

In the afternoon, at the Section on Practice of Medicine, Materia Medica and Phy-

siology, about 150 members were in attendance.

Dr. John H. Musser, of Philadelphia, occupied the chair. In the absence of the Secretary, Dr. George Dock, of Galveston, Tex., was elected to fill that position. The Chairman called attention to the rules governing the proceedings of the section and proceeded to read his Annual Address. He began by alluding to the epidemic of influenza and its effect upon the profession and described the improvements made in all branches of medicine and the increase in time and knowledge which the modern methods of medicine require of physicians. He also called attention to the great advantage of trained nurses in private practice and approved the suggestion of the senior Dr. Gross of having training schools in small localities. He spoke in support of the continued study of old remedies and deprecated the aimless experimentation characteristic of the day. He thinks we should make a closer study of the individuality of the patients as affected by the new conditions resulting from the amalgamation of the races by the immense immigration of the times and the high pressure of modern civilization.

Dr. De Saussure, of Charleston, S. C., read an essay embodying the results of the clinical study of twenty-five cases of

Filaria Sanguinis Hominis.

The doctor showed the heart of a dog, an animal particularly favored by filaria, containing an innumerable amount of the parasites.

Dr. Lovering, of Ohio, called attention to the similarity existing between the symptoms of trichinosis and those of Dr. De Saussure's patients.

Dr. Kelly, of Baltimore, spoke of cases observed in Baltimore.

Dr. De Saussure, in closing the discussion, said he thought all cases found in the North had originally come from the South.

Several papers announced on the programme were not read, owing to the absence of the authors.

Dr. C. H. Shepherd, of Brooklyn, N. Y., read a paper on

Rheumatism and its Treatment by the Turkish Bath.

He strongly advocated the treatment, admitting that it could only be carried out in special institutions, and cited several cases showing the advantages of the method.

Drs. Ulrich, Didama and Bailey discussed the paper, combatting the ideas of the essayist from various standpoints.

Dr. J. W. Davis, of Smyrna, Tenn., read a paper on the

Use of Calomel in Some Forms of Dysentery.

It called forth an animated discussion, in which the following participated: Drs. Dawson, Ulrich, Woodhull, Sloan, Didama, Musser and Davis.

The section then adjourned to meet at 2.30 o'clock. The principal feature of the day's session was a discussion of the continued fevers of the South.

In the Section on Medical Jurisprudence nearly all the time of the session was taken up in the discussion of alcoholism in its legal relations.

The President, Dr. T. B. Evans, of Baltimore, opened with an address on

Responsibility in Dipsomania.

He said that, at the present period, when attention of the whole civilized world is directed to alcoholism it is right and proper that some expression should go forth from this body on the subject. It is hardly necessary to portray the consequences that follow the improper use of alcohol. It is somewhat singular that long ago some effort to restrain this great evil was not made, for evils of much less magnitude have received attention. He called attention to the baleful influences of alcohol, both on the votary and his descendants. The thirst that follows the use of alcohol shows that it causes the system to throw off water from the tissues. The brain has a great per cent. of water and is consequently more affected accordingly. As the nerve centres are most easily affected it is not difficult to imagine the permanent evil result. Every habitual drunkard arrives at a stage of chronic affection of the brain where we have a morally depraved and physically unsound man. The habitual drunkard is more or less insane. He cited authorities to support his theory. The position was taken that the dipsomaniac was an irresponsible being with no sunshine, no gladness, but one thought in his brain, the desire for alcohol; that supplants all things else. He claimed that the dipsomaniac should be as much exempt from responsibility as any other maniac. Chief

Justice Coke claimed that a drunkard was doubly guilty, and a recent decision of a learned judge upholds this theory. Decisions of this character are unjust. They belong to the dark ages. There are many incompetent judges and still more incompetent jurymen, and again the physician is incompetent to testify in insanity cases unless he has had a special training. The question is not one for a judge to decide without competent and unbiased evidence. He thought the time was approaching, as shown by the signs of the time, when the dipsomaniac should have justice. A man may not be responsible for acts while drunk. He may have been in an enfeebled condition when he took a drink and very little alcohol made him drunk. There must no longer be a contest between law and medicine. Dipsomania must be properly diagnosed and explained.

A paper by Dr. Norman Kerr, of London, on

The Need of a New Criminal Jurisprudence Affecting Inebriety,

was then read by Dr. Everts.

The paper cited that during the past twelve months there had been two death sentences, one passed on a French soldier for striking a superior officer, the other a man in England for killing a woman, when the parties were drunk at the time they committed the deeds, and it is a scandal to our justice. As to who is to say when a man is drunk it is a difficult problem, not only to the ordinary justice or policeman, but to the practitioner himself. It is difficult, because alcoholic symptoms or those not of alcohol are present at once, and police proceedings should be had with sufficient safeguards. Persons repeatedly before the police court for inebriety deserve attention. The man is confined in quarters often better than he is accustomed to, and deprived of drink. Then, after a short space of time, when he has recuperated sufficiently to commence drinking again, he is turned loose. The police court and work-house make up a school of inebriety. The wife and family of the inebriate are often terribly punished. The writer was strongly opposed to punishing a criminal for a crime when unconscious of his actions from alcoholic stimulants, though where a man got drunk to commit a crime, if such things were ever done, his drunkenness should be no excuse. Our criminal procedure in regard to crimes committed by persons under the influence of alcoholic drink should be radically reconstructed. He thought that the habits of a man's ancestors for at least two generations back should be considered in determining his guilt. From only one point of view—that of economy, because it is cheaper to hang a man than keep him—should our laws regarding neuchonology be reconstructed.

Dr. T. D. Crothers then read a paper on

Some New Medico-Legal Questions Relating to Inebriety.

He agreed with the position taken in the other papers. The present view of the law is not supported by science, and the time has come when we should free ourselves from the dogmas of the court-room. The medical expert has nothing to do with the law; he should study to determine and present the facts alone. As to how far the testimony of inebriates can be trusted as to what they see while in that condition, he cited six instances where drunken men, or men partially intoxicated, have testified in court. He thought this testimony should be received guardedly. Professional and scientific men soon recognize in themselves the evil effects of alcohol. The man thus impaired is in the first stages of paralysis. His senses are dulled; and in his testimony there are many circumstances to be considered. Cases were cited where men under the influence of liquor had confessed to having committed crimes with which they had nothing to do, and the conclusion reached was that the statements or impressions of the drunken man regarding himself is not competent unless sustained by collateral circumstances. The final consequences of alcoholism are caused by a disease that commenced with the first glass of alcohol. The brain of the inebriate and of the moderate drinker are both alike weakened. He did not think a man could plan a crime and then get drunk to commit it. The mental condition and circumstances and many other questions are to be considered in determination of a man's responsibility or irresponsibility.

Dr. N. S. Davis, of Chicago, Chairman of the Committee on Meteorology, read a report on the meteorologic conditions and their relations to the

Epidemic of Influenza

and some other diseases in Chicago during the

six months ending March 31. His paper was long and composed of carefully-compiled statistics and meteorological observations bearing on the epidemic, with concise statements of the symptoms of the disease. Much was in tabular form. Dr. Davis was of the opinion that had the people of Chicago known nothing of the influenza prevailing without, its appearance in Chicago would have occasioned no unusual remark. Similar cases appear annually and are called winter cholera.

In the Section on State Medicine, Dr. John B. Hamilton, Supervising Surgeon-General of the Marine Hospital Service of the United States, Chairman of the Section, read an address.

State Medicine and Hygiene.

He said the Marine Hospital Bureau had devoted the last year to increasing quarantine facilities for vessels, publishing a weekly abstract of sanitary reports and increasing the facilities for laboratory work. There are two laboratories. Among other interesting observations made were the experiments of Dr. Kinyoun on the value of cobra poison as a cure for cholera.

The recent act of Congress to prevent the introduction of contagious diseases from one State to another and for the punishment of certain offenses was quoted in full, and the case of the State Board of Tennessee interfering with Kentucky was cited as the only case yet tried. The necessity of a stricter supervision of immigrants was never more manifest than now. It was stated that Key West is in danger of becoming a centre for the dissemination of yellow fever. This arises from the plainest neglect of hygienic rules. The use of cesspools within the city limits, bad water, lack of drainage, etc., being cited.

The influenza epidemic was said to be one of the most wonderful phenomena of nature. Its rapid spread from St. Petersburg, Russia, in November, 1889, all over the world was unprecedented. The American legation is trying to ascertain the circumstances of its origin. It has invaded every country, from north to south, even animals being attacked. La nona was described and attributed to the same causes as influenza, being regarded as a combination of pneumonia and cerebro-spinal meningitis. Leprosy was spoken of at length. Strict segregation, entire separation of the sexes and rigid enforcement of the immigration law was recommended. Leprosy is only slightly contagions, but inoculable. The country will not suffer if leprous immigrants are denied admission.

Reports of Clinics.

NEW YORK POST-GRADUATE MEDICAL SCHOOL.

CLINIC FOR DISEASES OF CHILDREN.—PROF. J. H. RIPLEY.

Congenital Heart Disease.

This patient was a girl five and a half years old. The students were asked to note what seemed abnormal in her appearance. One suggested that she was micro-cephalic. The head was measured in its largest circumference (which is always over the occipital prominence) and found to measure nineteen inches. The head of a child of this age should measure about twenty inches. Dr. Ripley said her head was therefore small, but not pathologically so. There should be observed a distinction between an abnormally (unusually) small head and one whose diminution in size denoted disease. Had the circumference of the head in this girl been but seventeen inches, it would be regarded as a serious condition; as it was no special significance could be attributed to the size of the patient's head. It was taught by some authorities that the head did not increase in size after the sixth year. This Dr. Ripley believed to be erroneous; as all who wear hats could testify. It was true that the greatest growth of the head took place during the first year or fifteen months of life. After the sixth year the head continued to grow, but not very much. At this age its circumference was usually twenty-one inches, or a little over.

Attention was now directed to the cyanosis of the patient, which was very marked in the finger-tips, which were also club-shaped. This was really a very prominent symptom, and one of such importance that Dr. Ripley had each member of the class observe it closely. The causes of this condition occurring in a child of this age were then enumerated: 1. Chronic cardiac disease, whether congenital or acquired: and diseases involving the heart and great vessels. 2. Malformations of the large pulmonary blood-vessels.

3. Phthisis pulmonalis. 4. Rachitis. 5. Pleurisy with effusion: this being a most important cause, not *per se*, but in its consequences and amenability to treatment.

Proceeding to the history of the case, it was learned that the mother had had three children and no miscarriages; that the first child died when four days old, from what her physician told her was bronchitis; that the second child, the present patient, was born thirteen months later, and without medical assistance. For one hour the child lay in the bed, with the cord uncut, and giving no sign of life until the arrival of the physician, who, however, resuscitated the infant in a short time. The third child, the youngest, is healthy. When the patient was nine months old she had a "cold," which lasted but a few days. She never had diphtheria, scarlet fever, measles or chicken-pox, and had been vaccinated. Her bowels had been regular and her urine of usual quantity. The mother believed the child to have been perfectly healthy until twenty-seven months old, when, her face being somewhat swollen, she brought her to a physician, who told her the baby had heart disease.

The child is inclined to be listless, and never plays hard; yet she has never shown what the mother believed to be actual illness, though she has never had a hearty appetite.

Palpation and percussion showed the heart in normal position and not increased in size, with impulse rather weaker and more diffused than it should be. The arterial tension was low; the pulse, 90. A loud systolic murmur was heard over the cardiac region, with greatest intensity at the apex. The murmur was also heard behind, at the angle of the scapula. With the history of no acute sickness and the presence of this murmur, the conclusion was that the patient was suffering with congenital heart disease.

The different forms of congenital heart disease were given as follows:

1. Patent foramen ovale—a condition frequently cited and probably not so frequently present. It should be borne in mind that other conditions will produce the same train of symptoms. And as a matter of fact *post-mortem* examinations more often reveal other abnormalities in so-called cases of morbus ceruleus. And, on the other hand, it is frequently observed at the autopsies of infants that this foramen is still open, and yet the baby during life had shown no signs of heart trouble. Autopsies in cases of congenital heart disease are comparatively rare, however, and positive facts with reference to this condition cannot be well formulated.

2. Malformations of the valves of the heart; more seldom found, however, than

3. Malformations of the septa, and particularly of the auricular septum. These lesions are usually near the base of the heart, and this is explained by the fact that in fetal life the septa close from below upwards.

The causes of congenital heart disease were divided into

1. Arrest of development and abnormal development, and

2. Intrauterine inflammations.

A sufficient number of hearts of children at birth have been examined, showing recent fibrinous exudations, to prove that endocarditis can occur in fetal life; and it can well be believed that arrest of development may sometimes be due to a pre-existent inflammation, as would appear in many of the specimens seen in museums and described in medical literature.

That diseases are communicated directly from the mother to the fetus, everybody knows. Dr. Ripley, in this connection, referred to a child born while in convulsions, the mother at the time suffering from uremic eclampsia. The most frequent cause of abnormal development and arrest of development is undoubtedly syphilis, and the most frequent cause of inflammatory disease is uremia—nephritis in the mother.

The exact nature of the lesion in the case before the class was doubtful. Dr. Ripley did not consider the murmur to be produced by mitral regurgitation; it was too superficial and too diffused. Fortunately an incomplete diagnosis does not make the therapeutic indications less clear. The worst feature in this case was the cyanosis, the imperfect circulation; and therefore efforts should be directed towards toning up the heart. The child should have good food, fresh air and moderate exercise. Digitalis (principally) and the other heart tonics if digitalis disagreed, should be administered in sufficient dose and for a sufficient length of time to render the action of the heart at all times adequate to perform its work.

One cannot always obtain as clear a history as this case gives of absence of any post-natal disease that might be or might cause endo-

carditis. In a child six months of age with a similar condition of the heart, the probability is always strong that the disease is congenital; after this age it is often a most difficult thing to determine when the heart trouble began.

LONDON LETTER.

Sir William Jenner.—Tuberculosis in Meat and Milk.—Hypnotism in Surgery.—Color-blindness and the Board of Trade.—The Telechrome.—Mr. Gladstone's head, and Bony Enlargements.—Zucci, the Faster.

Sir William Jenner has given up his lucrative practice and intends seeking retirement in the country. Few men have the resolution to take such a step until compelled by age or other incapacity, and this example might be more widely followed with advantage. It is only by retirement of the seniors that the subalterns get their chance of promotion. Sir William, moreover, withdrew from the harrassing work of a fashionable consultant, while still in full possession of his distinguished abilities. One is, therefore, glad to hear of his intention to gather together and re-edit the scientific and other papers scattered over many years of active life. His name appears in the register as a fellow of the Royal College of Physicians, 1852, thirty-eight years ago. During that period the world has witnessed many changes, both social and professional. Among the brilliant men of the century Jenner's name will be in the foremost rank.

A good deal of attention has of late been drawn to the question of the spread of tuberculosis through infected animals. As might be expected the meat dealers are up in arms. The question, however, is one that affects the national wealth too closely to be thwarted by the action of an interested class. The discovery of the tubercle bacillus, by Koch, has given sanitary reformers a firm basis for future operations. Who would have thought that the laboratory experiments of a German philosopher could have so profoundly affected the markets of the world within a few short years? It is but another weighty argument of the benefits conferred by science on the community. The cost of an iron-clad or an eighty-ton gun would suffice to keep a hundred simple, earnest men of science for a lifetime. Yet governments, which are ready to spend money like water over national defences, descend to driblets when scientific endowments are concerned. It is to the popular education that we must look hopefully for future action in these matters. Let the people once clearly grasp the fact that the butcher and the milkman may carry the seeds of consumption into their homes, and radical changes in those trades must quickly follow.

Hypnotism is engaging a good deal of attention in medical circles, and some of the journals seem inclined to take the matter up seriously. One may perhaps fairly doubt if enough use has hitherto been made of the undoubted influence of animal magnetism, or "mesmerism," as it was formerly called. A short while since, at Leeds, a number of leading medical men and dentists of the district, met together to witness surgical and dental operations performed upon subjects under hypnotic influence. In one case a woman of twenty-five was thrown into a slumber "at a word" from the hypnotizer and told to submit to have three teeth drawn by a dentist present, and at the same time to do everything required of her by the operator. While the teeth were being extracted there was no expression of pain on the face and the patient uttered no cry. When ordered to awake she declared she had no pain, and had felt none during the extraction. She was again hypnotized and ordered upstairs to the waiting-room, which she was reported to have done as a complete somnambulist. Another case was that of a girl, nineteen years old, who had already been treated painlessly under hypnotism for an abscess of the cheek. On this occasion sleep was induced by reading a brief order to that effect. The patient then submitted to a long operation during which sixteen stumps were removed, and awoke with a smiling declaration that she had experienced no pain. Other proceedings included removal of an exostosis from the great toe of a lad eight years old, and excision of tonsils in a highly sensitive girl, fifteen years old. One well-known surgeon present went so far as to say, "I feel sure that the time has now come when we shall have to recognize hypnotism as a necessary part of our study." In a letter of apology for non-attendance Dr. Clifford Allbutt says he remembered the

time, thirty-five years ago, when Liston performed serious operations, using hypnotism as the anæsthetic. After all this evidence, a full inquiry is certainly desirable, whether or not, as some enthusiasts maintain, hypnotism is destined at no distant date to supervene chloroform for many surgical purposes. Before that day arrives, however, it will have to be proved that every one can be "brought under" by suggestion as they are now by anæsthetic drugs.

Color-blindness and its proper testing has lately been much in evidence. It has been proved that year after year men who are color-blind have contrived to pass the Board of Trade's color tests, which are painted on card-board and sold for a few pence. After a little practice at a wool shop a candidate may learn to name the official test colors, namely, red, green and black. The subject has been discussed from one end to the other before the Society of Arts, and there can be no two opinions as to its important practical bearing. The color-blindness of officers on watch may account for many of those mysterious collisions at sea where the two vessels have been long in full sight of each other. Confusion of starboard and larboard lights means steering at random among no uncertain perils. The important practical suggestion has been advanced that all youths entering on a sea-faring life should be subjected to a stringent examination as to color-sense and other physical defects of vision. By this means the waste of valuable time entailed by a later discovery of incompetency would be avoided. The possibility of the color-blind educating themselves to pass a perfunctory test applies with even greater force to railway servants, who are allowed to present themselves several times for examination. An ingenious instrument has been lately invented for their especial benefit. It is called the "telechrome." The chief claims are, that it gives standard intensities; that lights are grouped in perspective, and that obscuring media are applicable to represent actual conditions of fog or mist.

The increase of size in Mr. Gladstone's hat has provided a fruitful theme for the journalists. Some time back the ex-premier confided to a friend the fact that he now found the head-gear of an official dress, that fitted perfectly a dozen years back, far too small for wear. Most of the pressmen seem to have jumped at the conclusion that the great stateman's brain must have taken on a sudden development in his old age. It is tolerably well established that the brain does not expand after two-score, so that in more scientific circles judgment on the point has been more cautious. Well-marked, general bony enlargements are rare, localized ones still more so, and any change in the skeleton of so prominent a figure in the world's history is hardly likely to have escaped observation. The real explanation is probably simple. As men get older they push their hats further down on their heads, presumably for the sake of warmth. Caricatures are generally founded on exact observation, and every one recognizes the truth of the picture of youth with hat perched on the top of the head, while age wears it reaching well down over eyebrows and nape of neck.

At the end of thirty days Zucci, the faster, seems in a bad way. He has lost in weight and spirit and taken to his bed. The manager of the Aquarium has received, so it is said, an unofficial intimation from the authorities that in the event of a fatal issue he will be held responsible. Were the misguided fasting man a pioneer he might be entitled to sympathy; as it is, he is looked upon, to use plain Saxon, as a misguided fool.

PERISCOPE.

Burn-Ulcer of Leg Treated by Grafting with the Skin of a Dog.

Mr. Alexander Miles, late Resident Surgeon, Royal Infirmary, Edinburgh, showed a patient to the members of the Edinburgh Medico-Chirurgical Society, Dec. 4, 1889, whose case is of interest from two points of view. On the one hand, because of the extreme frequency with which such cases are met in practice; and on the other, in view of the unusual means adopted for the relief of the patient. The case is described as follows in the *Lancet*, March 15, 1890:

W. A——, aged ten, a school-boy, was admitted to the Royal Infirmary, Edinburgh, under the care of Mr. A. G. Miller, on May 24, 1889, suffering from an extensive ulcer on his left leg, the result of a burn. On April 22 (a month before his admission), while playing on the top of a boiler used in the preparation of cow's food, he slipped, and his left leg was plunged into the boiling mixture as far as the knee. He at once withdrew it, and ran home, which was only a

short distance. His leg was found to have been scalded all round from the middle of the patella to the ankle, the foot having been protected by the boot which he wore. He was put to bed, and treated by his friends with various household remedies. On May 23, after a month of this treatment, he was seen for the first time by a doctor, who at once sent him to the hospital. On admission it was found that the whole of the skin of the leg, from the level of the middle of the patella to the ankle, with the exception of a small island on the front of the tibia, measuring two inches by half an inch, had been completely destroyed. The greater part of the resulting ulcer was covered with healthy granulations, but there were a few sloughs still unseparated. These were soon got rid of by means of boric-lint poultices, and at the end of a fortnight the whole surface was covered with healthy granulations, but there was not the slightest attempt at cicatrization. As a sufficient quantity of human skin to cover in the large area could not be obtained, it was suggested that the skin of some animal should be used. Accordingly, with the co-operation of the friends of the child, we obtained a young greyhound. The animal was seven days old, and in color was black and white. On June 6, about six weeks after the boy met with his accident, the grafting operations were commenced.

The puppy having been killed with chloroform, Mr. Miles closely shaved the whole of the anterior abdominal wall and flanks, and then dissected up the flap of skin thus mapped out. The whole thickness of the true skin was taken, leaving the subcutaneous fat. Meanwhile the leg had been thoroughly cleaned by the nurse, and all bleeding from the granulations arrested. The skin taken from the puppy was cut into strips measuring about six inches long by half an inch broad, and firmly pressed into the ulcer in the long axis of the limb. Smaller grafts about an inch square were used to fill in spaces left between the larger ones. A considerable area over the inner side of the knee still remained bare, and to cover it the skin from the pup's tail was dissected up, unshaved. The dressing consisted of small pieces of protective applied next the grafts, with the edges overlapping to facilitate removal, as well as the escape of discharge, and outside this a few layers of unprepared gauze moistened with weak boracic lotion; the whole dressing being kept moist by a layer of gutta-percha tissue. Over all a good layer of corrosive wool and a firm bandage were applied.

Subsequent notes.—June 9: Ulcer dressed to-day—three days after operation. One small graft had distinctly sloughed, and came away on the dressing, but the others all adherent. Cicatrization had already commenced round the margin of the ulcer, and also round the island of the skin in the centre.—June 11 (two days later): A stream of lotion could be run on the grafts without disturbing them. The island had, through the medium of some grafts, become joined to the lower margin of the ulcer. During the next fortnight healing went on rapidly. Some portions of the long strips sloughed, but the smaller grafts all did well. It was interesting to observe that the graft taken from the tail, which was not shaved, behaved exactly as sponge does, by promoting granulations. The hairs round the margins seemed to stimulate the granulations, which grew up on to the surface of the graft, and then spreading, completely swamped it. A few small grafts of human skin taken from a young boy were scattered here and there to fill up gaps still left. These all did well.—June 28: One or two spots still remaining were covered with pieces of frog's skin, but without exception these failed to take. The frog was an old one.—July 18 (six weeks after commencement of skin grafting operations): The ulcer was entirely healed. The patient was, however, kept in bed for a week or two longer, and then gradually began to use the limb.—March 10, 1890, over seven months since the patient was last under treatment, the leg was useful as ever it was. There was absolutely no contraction in the cicatrix, except where the tail skin was planted, and there it is very slight. The color of the skin is uniform and very similar to that of the normal skin. There was no evidence of any development of hair or of cutaneous secretions. The ordinary sensation was as good as in the other leg, and the temperature of both is the same.

There are three main factors upon which the success of such a case as this depends—(1) the general condition of the patient, (2) the condition of the ulcer, and (3) the means adopted to hasten the healing of the ulcer. The only favorable point in the general condition of the patient was his age. His general health was very much below par, and it is to this fact that we must ascribe the absence of any attempt at cicatrization

before the grafting was begun. As regards the condition of the ulcer, nothing could have been more satisfactory. It was a typical healthy, granulating surface. The success of this case was mainly due to the means adopted to cover in the sore. I am not prepared to say that the skin of the dog is better than that of other animals; but this animal can readily be obtained, and yields a sufficient amount of skin for most cases. The important point, however, is the age of the animal selected. In the first few days of extra-uterine life the creature grows very rapidly, and by grafting a large area of young tissue, with a potentially great developmental power, we quickly cover in the ulcerated area, and so prevent the contraction which invariably results after extensive burns when these are allowed to heal without artificial aid.

The Treatment of Chronic Diarrhœa.

Dr. H. F. Vickery, in an article on the treatment of chronic diarrhœa in the *Boston Med. and Surg. Journal*, February 20, 1890, says: The occurrence, during long periods, of frequent loose alvine evacuations is associated with many different diseases. Thus it may be due to a simple enteric catarrh, or to amyloid degeneration, or to dysenteric ulcers; it is frequent in pulmonary tuberculosis, even when the intestine presents no tubercular lesions; it may be referable to gastritis, malaria, leucocythemia, uremia, hepatic cirrhosis or heart disease.

It is evident, therefore, that our therapeutic efforts must often be directed to the fountain of evil itself rather than to the malodorous stream which flows from it. In many cases, however, the diarrhœa, although merely a symptom, demands direct treatment, and in yet others, to cure it is to cure the patient.

1. The diseased part should be given rest.
2. Any tendency to abnormal fermentation should be corrected.
3. No fecal accumulations should be permitted.
4. Pain is to be relieved.

1. Taking up these four indications in order, rest for the bowels means the ingestion of such kinds and amounts of food as will tax intestinal digestion least. Yet, it is not wise to go to the extreme of too little nourishment. Starvation works admirably in acute diarrhœa, but not in chronic. Tell your patients to take five or six meals a day, and at each meal as much as they crave of the kind of food permitted.

As to their diet. The intestinal tract in health is concerned in the digestion of all three of the cardinal elements of food—fats, starches and albumenoids—the last, least to be sure, but yet not so far below the others that meat-broths seem to me any better borne than gruels. Milk (aseptic) has proved excellent. Scraped raw beef is praised by many, although dread of tapeworms has deterred me from recommending it. Oily food is to be avoided.

As to consistence, nothing must be swallowed that can mechanically irritate the intestines; and liquids are better than solids. I allow any sort of liquid food that is smooth —beef-tea, broths, milk and gruel, made largely of milk, from any kind of grain, provided it is strained through a fine cloth before being taken.

With convalescence, the patient may regale himself on boiled rice, soft-boiled eggs, toasted bread, steak, mutton and potato, gradually and tentatively resuming ordinary diet.

2. The intestines in health swarm with bacteria, and the natural processes of intestinal digestion border close on putrefaction. Hence some antiseptic is almost always a useful ingredient in the prescription for a case of chronic diarrhœa. Subnitrate of bismuth probably acts to some extent in this way, besides soothing the mucous membrane. Michailoff, of St. Petersburg, has recently reported the cessation of a diarrhœa which had lasted thirty years under the employment of salicylate of bismuth. I have also used carbolic acid (one-half grain in each dose), beta-naphthol (one-half to one grain), or salol (two and one-half to five grains). Thymol has also been praised (two grains three times a day), but in the one case in which I tried it, it was suspected of causing headache, although the diarrhœa improved while it was being taken.

3. It is not merely in chronic dysentery that fecal masses may cause mischief. The subject of a chronic diarrhœa should have a daily evacuation of the bowels. The simplest way to do this is to go to stool at a certain time every twenty-four hours, and at that time, if necessary, to take an enema of cool water. In some instances I have incorporated rhubarb with the diarrhœal medicine. In others I have written a separate prescription for fluid extract of cascara sagrada, directing the patient to substitute this

for his other remedy if the bowels become sluggish; this seemed particularly valuable in cases of chronic intestinal catarrh, where a history of alternate diarrhœa and constipation was given.

4. Pain is a symptom of varying prominence in chronic diarrhœa. The preceding directions go far to remove it, if present; but at the start, it is often advisable to add five minims of deodorized tincture of opium or a drachm of paregoric to each dose of medicine, omitting it as soon as may be. Sometimes the bowels are lame, so that motion is painful. Sometimes changes of temperature affect the patient disastrously. For both these conditions a flannel swathe is useful. And in severe cases rest in bed is demanded. The various astringents, such as tannin, sulphate of copper, alum, liquor ferri nitratis, and nitrate of silver, I have used little.

Where the frequent dejection of small amounts of mucus and blood with tenesmus, indicates the predominance of colitis, rectal irrigations through a soft tube passed high up, are both rational and efficient. Two or three pints of simple cold water used in this way does good. In it can be dissolved sulphate of zinc or alum to the amount of one grain to every four to six ounces of water; or two grains of nitrate of silver to a pint, can be injected every one or two days, if allowed to come away at once.

Rotation of the Heart and Torsion of the Aorta.

Professor Schröther, in the *Wiener Klinische Wochenschrift*, No. 15, describes a remarkable condition of the arteries in the case of a man twenty-two years old with insufficiency of the aortic valves. While at the femoral, the dorsalis pedis, and posterior tibial, the pulse, in conformity with the aortic insufficiency, was fairly large, distinctly hurrying and murmuring, at both radials, in contrast, the pulse was small and failed to present the other two peculiarities. The patient died in consequence of a facial erysipelas, and at the autopsy the explanation of the manifestation was found in the position of the heart, which was rotated upon its axis towards the left. The aorta from its origin to a point beyond the arch was twisted in the same direction and to such a degree as to produce a partial angle and distortion at the orifices of the large vessels as they were given off to the upper portion of the body; these received an imperfect supply of blood, and in this way the striking difference between the pulse of the arteries of the upper half and that of those of the lower half of the body was occasioned. —*Deutsche med. Wochenschr.*, April 17, 1890.

A Syringe for Bacteriological Work.

In the *Münchener medicinische Wochenschrift*, March 25, 1890, there is described a syringe devised by Dr. E. Stroschein for use in making injections for purposes of bacteriological study. The requirements of such an instrument are its sure and speedy sterilization, which implies a resistance to the action of powerful bactericidal agents, such as corrosive sublimate and high degrees of heat. Over a graduated glass tube for the reception of the fluid to be injected, slides a second glass tube, closed at its upper extremity and so connected with the first by means of a short cylindrical piece of rubber tube that the compartment remains air-tight when the one is pushed over the other. As the smaller tube has a small opening at its upper end, sliding the larger back tends to produce a partial vacuum in both tubes, and any fluid in which the needle is immersed will be sucked up into the smaller. On the larger tube pushing forward the air in it and in the smaller tube is compressed, and the fluid will be injected. The instrument is simple in construction, and, excepting the metallic needle and the ring of rubber, consists entirely of glass. It is readily cleansed, convenient of manipulation, and inexpensive.

Statistics of the Grippe.

At the recent Sanitary Convention, at Norristown, Pa., Dr. Benjamin Lee, the Secretary, reported that he had sent letters to about 6,000 physicians, requesting answers to several questions relative to the pandemic of influenza. Replies were received from 265 physicians, who reported a total of 37,275 cases, of which 26,302 were adults, and 10,973 children; 6,917 were nervous in their characteristics; 16,434 were catarrhal, and 5,829 inflammatory; 56 deaths resulted directly from the influenza and 205 indirectly, 117 from pneumonia, 8 from bronchitis, 42 from phthisis, and 21 from nervous affections.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

INVESTIGATION OF AN ALLEGED ABORTIONIST.

In another part of this number of the MEDICAL AND SURGICAL REPORTER we give the results of an investigation undertaken for the honor of the medical profession and the welfare of the community. A number of the subscribers of the REPORTER have complained of the injury done in Easton, Pa., by the suspicion that a regularly registered practitioner in that city was what is commonly known as an abortionist.

In the hope that this suspicion might prove unfounded, but with the belief that to make public the actual facts of the case would be doing a service to our brethren in the medical profession and to our fellow-citizens, an investigation was undertaken, and we give, without comment, its disclosures to the readers of this journal.

Nothing, we believe, is more likely to put a stop to a wrong than to bring it to the notice of the public in plain terms; and we shall always be ready to turn the light of the columns of the REPORTER on any evil which is properly a subject for investigation or comment by a medical journal.

THE JEFFERSON MEDICAL COLLEGE A THREE YEARS' SCHOOL.

The sixty-sixth Annual Announcement of the Jefferson Medical College calls attention to the fact that, with the Session beginning October 1, 1890, this well-known School joins the ranks of those which require three full courses of actual study from their students. As now arranged, the courses will be graded and will last six months and a half, from October 1 to April 15.

The inauguration of this change will be hailed with pleasure by all the friends of higher medical education, and will be a source of special gratification to the friends of the Jefferson College. The Faculty will look to the Alumni for earnest support in carrying out the principles which the College has adopted; and it is to be hoped that they will exert themselves to show that such a step meets the approval of all who have at heart the best interests of the College. Every medical school which has left the old two course plan behind and advanced to the position of requiring three courses of study has found that there are some difficulties connected with it, and in one lamentable case—that of the Bellevue Hospital Medical College—these difficulties frightened a strong institution into retreat and abandonment of what it had undertaken.

We have no idea that this can happen to the Jefferson College; but we think it right to call the attention of the readers of the REPORTER—many of whom are Jefferson graduates—to the fact that now is the time to show their love for their Alma Mater, by standing strongly by her when she needs and deserves the support of every one of them.

SPEECH FOR THE DEAF.

It is, perhaps, not generally known by parents of deaf children throughout Pennsylvania, that a boarding-school has been recently established in Scranton, Pa., to teach the deaf to speak and develop them mentally through lip-reading, where all classes of deaf children—those born deaf as well as those less afflicted—residing in Pennsylvania are admitted free. Oral teaching for the deaf, the system which in all countries but this is gradually supplanting all others, has its most complete application in this State in the Pennsylvania Oral School for the Deaf at Scranton. It is encouraging to know that the exhibit of this school at the Paris Exhibition of 1889 received a silver medal. This recognition is of the more consequence, as France, the country in which the sign language originated, has abolished its teachings and conducts the entire training of the deaf on the oral system.

This institution is under the care of Miss Emma Garrett, who has had long experience in teaching deaf mutes, and whose skill, patience and faithfulness in the work make her peculiarly well fitted for it.

We call the attention of physicians in Pennsylvania to the school at Scranton, in the hope that they may be able to spread a knowledge of the advantages it offers, without charge, to a most unfortunate class in the community.

STATE BOARD OF MEDICAL EXAMINERS AND THEIR EXAMINATIONS.

The REPORTER has repeatedly urged the importance of establishing in each State Boards of Medical Examiners to examine candidates before permitting them to practice medicine. It believes such boards to be for the highest interests of both practitioners and the public. By their operation it is hoped that worthy candidates may secure an honorable admission to the ranks of the medical profession, it is expected that unworthy candidates will be rejected and prevented from imposing upon the community. Under the present system of medical education, the Faculty which the student pays for his tuition practically decides whether he shall be admitted to practice or not; and just as long as this system exists, just so long will there be a temptation to inferior schools, desirous of patronage, to look too leniently upon defects which would seem serious in the eyes of an impartial tribunal. Owing in some cases to difficulties hard to overcome and sometimes to culpable disregard of right, the grade of instruction furnished at certain medical schools is of a decidedly inadequate character, while that of some of the higher class differs widely in its extent and comprehensiveness. And yet, apart from the supervision of State Boards of Medical Examiners, a graduate of the meanest institution in the land has in most States just as good a right, before the law, to undertake the responsibilities of the medical profession as the graduate of the most thorough educational establishment.

To correct the obvious disadvantages of such a state of affairs Boards of Medical Examiners have been created in several States, and we trust that other States will soon follow their good example. This experiment has, we believe, so far justified itself thoroughly; and yet from time to time complaint arises in regard to the way in which it operates in certain individual cases. One ground of complaint has been the asserted severity of the examinations. The *Southern Medical Record* recently referred to a charge that one of the State Boards "put before the applicants for license an array of questions that would have rejected almost any man who had been in the actual practice of his profession for any length of time."

If this accusation was brought by one of the men who gave such answers as we have recently cited for the information of the readers of the REPORTER, we need not wonder at or waste much time in considering it.

Still, it may be proper to advert to the fact that there is always some danger that examiners—especially if not practiced in examining—may err in attaching too much importance to failure in answering questions of a purely theoretical character, or that they may sometimes ask questions which are rather medical riddles than tests of fitness to discharge the duties of the physician.

It is with the utmost devotion to the principle of State Medical Examining Boards that we call attention to this point—not because we believe it has been actually overlooked, but because we would not seem indifferent to a feeling which may have some ground beside the natural chagrin of rejected candidates for license to practice, and because we would like all the State Examining Boards to be as near perfect as is possible.

ARISTOL FOR EPITHELIOMA.

The European Journals are beginning to contain a good many communications in regard to the action of aristol, which was described in the REPORTER, April 26, 1890. One of the most interesting and most recent is that by Dr. Brocq, in the *Bul. et Mem. de la Soc. Méd. des Hôpitaux*, May 1, 1890. Dr. Brocq presented to the Society a patient who had suffered for a long time with an intractable ulcerating epithelioma in the face. He had had this epithelioma since 1878, a period of about twelve years, and in that time it had progressed from bad to worse in spite of every effort that had been made to restrict its advances. When Dr. Brocq first saw the patient, he thought that nothing but a surgical operation could be of any use, and sent him to Dr. Championnière, who sent him back, stating that nothing could be done for him. Out of mere pity, Dr. Brocq then took him into the hospital and began treating him. He used concentrated solution of chlorate of potash; then powdered potash; and then, on account of the painfulness of these applications, he used an ointment of resorcin with one-tenth part of chlorate of potash. He then curetted superficially the edge of the ulcer; and in this way obtained a slight amelioration, but nothing satisfactory.

After this he decided to try the effect of aristol, which he had recently used with satisfactory results in another case. He made the first application on April 5. The result was almost immediate. In five or six days cicatrization was going on with great rapidity. In order to facilitate the process Dr. Brocq scraped superficially the borders of the neoplasm, removing the characteristic pearls of epithelioma. On April 25, when the patient was presented to the Society, twenty days after the treatment had been begun, the ulcer was almost healed, and Dr. Brocq was very confident that within a very few days the whole would be closed up.

This result of the action of aristol seemed to Dr. Brocq very remarkable, and decidedly superior to that which is ordinarily secured by topical applications in superficial ulcerating epithelioma. Aristol has an advantage over chlorate of potash in being entirely painless.

Brocq makes a very important observation in regard to the action of aristol, due appreciation of which may prevent disappointment and unjust criticism of the substance. This is that it may be expected to do good in superficial ulcerations, but not in deep ones. It is not a cauterant, and has not such an affinity for diseased tissues as some other substances have in superficial ulcerations; it seems to have a very remarkable curative power, producing cicatrization more rapidly than anything else with which he is familiar. It has a value in other forms of ulceration than the epithelimatous; and the experience of our colleagues on the other side of the Atlantic indicates that aristol is well worthy of a trial in this country, and that it is probably an addition of real value to the armamentarium of the physician and surgeon.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

INSOMNIA AND ITS THERAPEUTICS. By A. W. Macfarlane, M. D., Fellow of the Royal College of Physicians, Edinburgh, etc. 8vo, pp. xv, 366. London: H. K. Lewis, 1890.

The opening chapters of this interesting book are devoted to an explication of the physiology of sleep and to some general remarks on insomnia. The author discusses the phenomena of sleep and of its gradual onset, and its effects upon the body; he then refers briefly to the various theories as to its causation. None of these theories are regarded as satisfactory, but a moderate amount of anemia is looked upon as essential to sleep. Insomnia is defined as any interference with the depth or duration of sleep. The essentials to sleep are asserted to be sound, nervous structures, normal metabolism, adequate repose and rightly-adjusted work. Conditions which influence sleep, apart from sex and age, are temperament, habit, occupation, method of living, history (including hereditary tendency, etc.), season and climate. In successive chapters the author then treats of the insomnia depending upon affections of the nervous system, the alimentary canal, the liver, upon gout, affections of the circulatory and respiratory systems, febrile and general diseases, affections of the urinary system and of the insomnia peculiar to women. Each recognized cause of sleeplessness is treated separately, and appropriate treatment is given. The author is to be commended for suggesting a number of useful formulæ.

Dr. Macfarlane has an extremely helpful book on a subject already of very great interest and importance, and one which is bound to attract increased attention as each year sees the struggle for position and even for existence become more absorbing and exhausting. He who will have, must sacrifice something to attain, but a full knowledge of the ways in which insomnia is brought about and of the remedies at our command will enable the physician so to direct a patient's habits of life that the detriment to him from sleeplessness may be least.

ÉTUDES DE CLINIQUE INFANTILE; Syphilis héréditaire précoce; laryngite syphilitique; broncho-pneumonie par infection intestinal; prophylaxie de la rougeole et de la diphthérie a l'hospice des Enfants-Assistés. Par le Dr. Sevestre, Médicin de l'hospice des Enfants-Assistés. Avec figures dans la texte. Volume in 8vo, de 143 pages. Paris: Publication des *Progrès Médical*, 1889.

CLINICAL STUDIES OF INFANTILE DISEASES; Infantile hereditary syphilis, etc., in the Home for Assisted Children. By Dr. Sevestre, Physician to the Hospital for Poor Children. With illustrations. 8vo, pp. 143. Paris: Published by the *Progrès Médical*, 1889. Price, 3 francs.

By far the larger portion of this book is devoted to the study of infantile hereditary syphilis. The subject is dealt with clearly and extensively; the various manifestations of infantile congenital syphilis are discussed separately. The views of numerous eminent syphilographers are referred to, and the results of extensive clinical experience are given. Special attention is given to the laryngeal manifestations of infantile syphilis. The two concluding portions of the book, on a form of broncho-pneumonia, originating in an intestinal infection, and the prophylaxis of measles and diphtheria in the Home for Poor Children, are, properly, monographs on these subjects, and have no connection with the first part. Both, however, are well written. The book is illustrated with numerous clear cuts, and is well printed.

HOW TO EXAMINE FOR LIFE INSURANCE. By John M. Keating, M. D., President of the Association of Life Insurance Medical Directors. 8vo, pp. 211. Philadelphia: P. Blakiston, Son & Co., 1890.

The first part of this book is devoted to a statement of the nature of life insurance, the duties of the medical examiner and advice to him in conducting an examination of an applicant for life insurance. The methods to be pursued in examining the heart, lungs, liver, bowels, kidneys and nervous system are given concisely. The opinions of competent men in their special departments have been made use of by the author in compiling the book.

The second part of the book is made up of the printed instructions issued by the life insurance companies of this country to their medical examiners.

The book will be helpful to medical examiners, and we can recommend it to them.

Correspondence.

Diphtheria or Tonsillitis.

To the Editor.

Sir: In the Reporter for May 10, I see an Editorial on Follicular Tonsillitis, which discusses the diagnosis between it and diphtheria. The subject has been of great interest to me for some time as I have had so much tonsillitis in my practice for the last year. And why of so much interest? Because I find the old physicians and many of the young ones telling me every day that they have diphtheria, when I contend that it is not. I must say here that I saw two cases which perplexed me very much as to what it was, but I stuck to my diagnosis of tonsillitis. Is tonsillitis contagious? If not, then why did I have it going through a family? In some places it has only been seen in one member of the family, and again I find it in two or three and then stopping. We have no grayish membrane, but a yellowish-white tinge. The tongue is coated and the temperature ranges from 101° to 103°, the pulse from 120 to 140 in children, with headache and loss of appetite for a day or so. There is tenderness (externally) over the region of the tonsils, and often the glands of neck are swollen, at times to such an extent that it is hard to tell it from mumps. I have had some patients who, al-

though they were very sick, were out again in a few days. Diphtheria, in the first place, is very contagious, and if we see one case in practice we are very apt to find others, and some must be of the malignant type—not one, but many.

I have often heard other physicians say: "I can cure diphtheria;" and my thoughts were: "You think so, but, if the truth must be told, you did not have diphtheria to treat, but tonsillitis." Diphtheria is not a common disease and we do not see it every day. I hear of it now all around me and think it strange that others meet with the terrible disease and yet I do not see anything of it.

Ammoniated tincture of guaiacum will abort the symptoms of the disease I see, and the patients have all done well with simple washes, etc., and so I must say that I have my first case of diphtheria to see in my practice.

You speak of the friends wishing to know the nature of the disease. When I am uncertain, I tell them I believe it to be so and so, but it may develop into something else.

Yours truly,

DOCTOR.

Nona.

TO THE EDITOR.

Sir: Reading your Editorial of May 3, "Nona," explains a case I had, beginning April 19, when I was called to a child in convulsions which had lasted nearly an hour and a half, although the mother had used all ordinary family resources to cut them short.

The child, aged 4 years, had symptoms of "cold on the chest," for which the mother had been doctoring it for three days; but it had not been regarded as very sick. It had slept most of the time. On examination I found slight general broncho-pneumonia, high temperature, pulse 140, head retracted, eyes staring, pupils dilated and breathing stertorous. The child had passed urine and feces unconsciously.

In view of the fact that the child had already had all ordinary home treatment, I gave an inhalation of chloroform to relax the spasm and a hypodermic of tr. veratrum viride (Norwood's) gr. ii, and an enema containing 10 grains of chloral.

In an hour the pulse had fallen to 72; and as the child was able to swallow I prescribed:

℞ Tr. gelsemii . . . . . gtt. i
Potas. bromidi . . . . . gr. v
Potas. iodidi . . . . . gr. i
Syr. ipecac . . . . . gtt. v

M. Sig. To be taken every two hours until better; then every four hours.

In twelve hours the convulsions recurred and were treated as before. In seven days the child was convalescent.

The second case was a child eleven weeks old with broncho-pneumonia of both lungs. Meningitis developed on the fourth day, and the child died on the eighth day.

As this phenomena followed the *grippe* after an interval of about a month, as did the cases of nona reported in Germany, I feel that the same condition was present in my cases.

THEO. G. DAVIS, M. D.

Bridgeton, N. J.

Census of Hallucinations.

TO THE EDITOR.

Sir: May I ask for the publicity of your pages to aid me in procuring co-operation in a scientific investigation for which I am responsible? I refer to the Census of Hallucinations, which was begun several years ago by the "Society for Psychical Research," and of which the International Congress of Experimental Psychology at Paris, last summer, assumed the future responsibility, naming a committee in each country to carry on the work.

The object of the inquiry is two-fold: 1st, to get a mass of facts about hallucinations which may serve as a basis for a scientific study of these phenomena; and 2d, to ascertain approximately the proportion of persons who have had such experiences. Until the average frequency of hallucinations in the community is known, it can never be decided whether the so-called "veridical" hallucinations (visions or other "warnings" of the death, etc., of people at a distance) which are so frequently reported, are accidental coincidences or something more.

Some 8,000 or more persons in England, France and the United States have already returned answers to the question which heads the census sheets, and which runs as follows:

"Have you ever, when completely awake, had a vivid impression of seeing or being touched by a living being or inanimate object, or of hearing a voice; which impres-

sion, so far as you could discover, was not due to any external physical cause?"

The "Congress" hopes that at its next meeting, in England in 1892, as many as 50,000 answers may have been collected. It is obvious that for the purely statistical inquiry, the answer "No" is as important as the answer "Yes."

I have been appointed to superintend the Census in America, and I most earnestly bespeak the co-operation of any among your readers who may be actively interested in the subject. It is clear that very many volunteer canvassers will be needed to secure success. Each census blank contains instructions to the collector, and places for twenty-five names; and special blanks for the "Yes" cases are furnished in addition. I shall be most happy to supply these blanks to any one who will be good enough to make application for them to

Yours truly,

WM. JAMES.

Harvard University,
Cambridge, Mass.

NOTES AND COMMENTS.

Investigation of an Alleged Abortionist.

On May 8, 1890, a representative of the MEDICAL AND SURGICAL REPORTER had a number of communications, by letter and by personal interview, with Dr. Howard Fackenthal, of Easton, Pa., in regard to a proposition that Dr. Fackenthal should perform an abortion upon a young woman, said to be two months pregnant, no proper medical reason being assigned for the operation. Our representative opened the investigation by sending the following letter—which is now in our possession—to Dr. Fackenthal.

EASTON, PA., May 8th, 1890.

DR. HOWARD FACKENTHAL.

Dear Sir: I called upon you twice yesterday, but unfortunately found you out, and as I wish to be sure of you, I send this note. I have a most embarrassing case for you. A young lady friend of mine has become a victim of unfortunate circumstances at some one's hands and is now about 2 months with child. I regret to say that I am implicated to the extent that the lady's honor is in my hands, and I am naturally anxious to give her all that skill or money can afford to save her from disgrace.

In plain words she must be relieved of the child. Circumstances are such as to render any other step impossible. Can and will you do this for us? The lady is very strong and ready to submit to anything. Will, however, the operation be very painful or involve much danger? Finally, what will it cost me?

Neither the lady nor myself are from Easton, but an adjacent town. Social connections render it necessary that this matter should be kept from all ears. I therefore must rely upon your entire confidence. The lady is not here, but I can bring her if necessary, and will follow your advice entirely. Kindly send reply by messenger. I do not wish to be seen calling at your office so soon again, and must leave for home today. Yours truly,

W. CLARK.

P. S.—For obvious reasons, which you will readily understand, I would feel obliged if you would return me this letter.

To this Dr. Fackenthal replied in the following letter, of which we present a *facsimile:*

Dr. H. Fackenthal.
Office: Cor. Fifth and Northampton streets.
Residence: 38 South Fourth street.

EASTON, PA., May 8, 1890.

MR. W. CLARK.

Dear Sir: The same obvious reasons that make you want your letter returned make it necessary for me to *not* write—you can call upon me if you desire. I will be in from two to four or if you prefir you can fix another hour or even place. Confidence begets confidence. I return with this your letter, which is of course propper. Please destroy this also—your coming often would excite no coment if you are a stranger you would be taken for an agent or as from ten to thirty callers per day is a usual thing no one notices unless they call with ladies either younger or lovers. By seeing me you can learn what you want.

Your

H. FACKENTHAL.

P. S.—Please remember you are a perfect stranger to me—and transchent. I am permanent. H. F.

An interview with Dr. Fackenthal, lasting about an hour, followed, in the course of which our representative described the case of the imaginary person, said to be pregnant, and attributed to her the well-known symptoms and signs of early pregnancy. Dr. Fackenthal went quite fully over the whole subject, under the leading of our representative's questions, and assured him that he would do the operation; that it was not painful or more dangerous than an ordinary child-birth; that it required no cutting; that the woman would experience no result from it for about five days; and that immediately after it was performed she might go to a ball and dance the same evening. As to the effect upon the child, Dr. Fackenthal said that his operation did not kill it but blighted it "as a worm blights an apple and makes it mature more quickly and fall." He showed our representative the illustrations of the generative organs of woman in *Gray's Anatomy,*

and with their help explained the steps of his proposed operation. He also showed the instruments which he said he was in the habit of employing.

Our representative, in order to learn if Dr. Fackenthal made a regular practice of performing abortions, said to him: "Doctor, pardon me for asking it, but I don't want to think that I am entrusting the life of this woman to a novice who has never done this operation before." To this Dr. Fackenthal replied: "Oh, no, I have had considerable experience in cases of this kind. Diseases of women have always been my specialty; but I have gradually drifted into this work, and have helped out a great many people."

Dr. Fackenthal then showed our representative the instruments which he said he was in the habit of employing. One was a large return-current canula about one-third of an inch in diameter, with a screw tip at the proximal end for the attachment of a syringe. With this, he said, air or water could be injected into the womb. He showed also a heavy flexible uterine sound, which he said he sometimes used. A third instrument was a sound with a sliding scale with which to measure the depth of the cavity of the womb. In the operation, he said, the canula was to be pushed through the cervix, between the membranes and the wall of the womb, clear up to the fundus; a metal washer on the canula was then pressed up close to the cervix, and the instrument was swept round the membranes, forcibly tearing loose all connections between the mother and child. Occasionally, Dr. Fackenthal said, it was necessary to inject air into the womb, to accomplish this. He said that the membranes were not ruptured in his operation, and that its effect was not immediately perceived, but produced dislodgment of the fetus and the membranes at the end of about five days. In cases seen very early in pregnancy he said he used the sound described above, instead of the canula. He said that the instrument he showed was specially designed by him and made to order, in New York.

On being questioned as to where and how the operation he had agreed to perform at the suggestion of our representative, could be carried out, Dr. Fackenthal said that the young woman might be taken to almost any "whore-house" and stay; but that, since a fatal case had taken place in a hotel in Easton not long ago, the houses of prostitution in that place refused to have anything to do with them.

He proposed that the young woman whose case was being considered should come to Easton alone, or ostensibly so, and have the operation performed by him at his office. He said that, as its effects were not immediately perceptible, she could then return to her home for four or five days; then she should go to Philadelphia to some small hotel, where she and the representative of the REPORTER should register as man and wife, and Dr. Fackenthal would come as soon as he was notified that the labor had begun, and would see the woman through. He said no nurse would be needed. All the young woman would have to do would be to keep quiet for fully two weeks.

With a parting injunction to our representative that the operation should be performed as soon as possible, the interview closed.

It was followed by another letter from our representative to Dr. Fackenthal—of which we have a *fac-simile*—and one from Dr. Fackenthal to him—of which we have the original—which we do not think it necessary to publish just now.

Treatment of Hemorrhages.

In an article on the treatment of medical emergencies, in the *University Medical Magazine*, Jan., 1890, Dr. James Tyson, in referring to the treatment of hemorrhages, says that hemorrhages from the lungs, which are in the main confined to tubercular consumption, occur in two different stages of the disease, and have a very different significance. They may occur early, when the blood-vessels in the neighborhood of a tubercular infiltration, weakened by a tubercular deposit in their walls, yield to a distention from collateral hyperæmia. In such a case the hemorrhage is rarely large, and so far from being harmful is often a relief to a congestion producing dyspnœa and oppression. The greatest danger is the irritation and even inflammation which may be brought about by the presence of small coagula in the bronchioles and their insufflation into still pervious air vesicles. This danger escaped, the hemorrhage is harmless.

The second form of hemorrhage is much more serious. It occurs late in the disease and is due to ulceration through the coats of

a blood-vessel of considerable size, the vessel being either in the walls of a cavity or traversing it. Such a hemorrhage is dangerous and not infrequently fatal. Prompt measures are therefore to be taken to relieve it. The thorax should be kept raised and absolute quiet should be observed. This is further secured by a full dose of an opiate if it will be well borne by the patient. Of internal remedies the time-honored one of salt is of uncertain value, but in the absence of anything else may be swallowed in the dose of a teaspoonful, repeated in a few minutes if the hemorrhage continues. Gallic acid in 15-grain doses every ten or fifteen minutes is a more rational measure and should be substituted for the salt as soon as it can be obtained. Hypodermic injections of ergotin in doses of 5 to 10 grains in water may be given simultaneously, and should be repeated daily or twice daily where the tendency to hemorrhage continues. Their object is to bring about contraction in the blood-vessels. Other astringents, such as acetate of lead in 3-grain doses, may be used under the same circumstances, as it would not be safe to use this drug in any quantity sufficient to bring about an immediate effect. The application of cold over the bleeding site is especially recommended by German clinicians, but one must be sure first of the situation, which is not always easily ascertained. Cold should be applied in the shape of ice in bladders or rubber bags, so that the clothing shall not become damp, or of cloths wrung out in cold water. A more extreme measure, to be resorted to when others fail, is to throw a ligature around the larger limbs, cutting off the return of blood by the veins while the outflow through the arteries is still permitted. Such a course will withdraw blood from the lungs and lessen the tendency to hemorrhage.

Hemorrhage of the stomach and bowels occurs usually either in cirrhosis of the liver or in typhoid fever. When due to cirrhosis the hemorrhage is either from the stomach or upper part of the small intestine. When due to this cause it is more apt to be a capillary oozing, although sometimes quite copious. Under these circumstances blood is both vomited and discharged by the bowel. Such hemorrhages are also not infrequently a relief to the portal congestion. Often they may be permitted to subside of themselves. When treatment is required it is more promptly efficient than that for hemorrhage from the lungs, because more directly reached. Tannic acid may be given in 15-grain doses every 10 or 15 minutes, or at longer intervals according to circumstances. In the absence of this drug even alum may be used in the proportion of a teaspoonful to a glass of water and taken in four doses at short intervals. Hemorrhages from the lower bowel occur from typhoid fever and are much more dangerous. The immediate cause is ulceration through a blood-vessel of smaller or larger size. They are always regarded as a serious complication of typhoid fever, but recovery is still not infrequent. Serious symptoms are a reduction in temperature, loss of pulse and other signs of collapse.

Hemorrhages from the bowel are treated by absolute quiet, cold compresses, or ice bags to the abdomen, and the use of food the most bland and unirritating. Indeed the intervals between food should be made as long as possible. It is doubtful whether drugs administered by the mouth reach the seat of hemorrhage in typhoid fever, but tannic acid may be given as in hemorrhage from the stomach, large doses being very much more apt to enter the bowel.

Nasal hemorrhage frequently calls for the physician's aid. It occurs also in connection with typhoid fever and cirrhosis of the liver, but also in association with heart disease, and sometimes cannot be accounted for. The simplest measures for its relief are snuffing up cold water or solution of alum in water, a teaspoonful in eight ounces, injecting hot water into the nasal passages, and the use of ice externally. The dropping of a cold key down the back of the neck is a domestic remedy whose success is not without a rational explanation. The sudden impression of the cold key through a reflex action may cause a contraction of the blood-vessels and then the hemorrhage ceases. Plugging the nares with a Bellocq's canula or other means should be practiced when all else fails.

The checking of nasal hemorrhage, as indeed of all hemorrhage, is aided by keeping the patient quiet in bed, and sometimes when there is a tendency to recurrences it is necessary to keep him on his back for several days.

Hot Air Cure for Consumption.

We give below the summary of an interesting paper read by Wales L. Cary, M. D., Physician of the Brooklyn Throat Hospital,

before the Medical Society of the County of Kings, at its meeting in Brooklyn. A perusal of these conclusions to be drawn from the statements of the paper will convince any one that this so-called Dr. Louis Weigert method of hot-air cure for consumption is a snare and delusion, which may be very dangerous.

I. Comparative pathology and the natural history of pulmonary tuberculosis in man indicates that the most favorable temperature for the *intra-pulmonary* development of its bacillus is much higher than 99.5° F.

II. Tubercular bacilli, in a favorable soil within an animal organism, are not attenuated nor their development arrested by temperatures which are inimical to them in artificial or non-vitalized culture-media, but even rendered more virulent and more rapidly reproductive.

III. Temperatures demanded for effective disinfection or discontinuous sterilization by dry heat are impracticable and injurious to the animal organism.

IV. It would appear that Dr. Weigert is mistaken in supposing that the residual air is heated much above 113° F.; and that, in fact, there is but very slight, if any, elevation of the intra-pulmonary temperature. Recent advices from Germany inform us that accurate measurement of the actual elevation of the lung temperature is but from a half to one degree.

V. If it were possible to produce and maintain, even for a short time, an intra-pulmonary temperature approaching 113°, there would be produced, independent of the effect upon the lung-tissue, grave degenerative changes in the blood and entire cellular elements of the body.

VI. At temperatures far short of those claimed, there would be produced an auto-infection and accumulation of excrementitious products, by diminished respiratory capacity, directly deleterious to the organism at large, and indirectly embarrassing to those nutritive activities upon whose integrity all hope of permanent benefit to the consumptive must rest.

VII. The factor productive of the benefit arising from the Weigert method is the *dryness*, rather than the heat, of the inspired air; and this desiccating action cannot be obtained except the temperature of the inspired air be as low at the upper as in the deeper parts of the lung. Of further benefit are pulmonary gymnastics, the psychological effect, and possibly in some cases a favorable action upon the bacteria in the larger bronchi.—*American Analyst*, April 17, 1890.

Precautions against Trichinosis in Germany.

Professor Proust, director-general of the sanitary service of France, recently reported to the commission the following instance of the danger of trichinatous meat, and the severity with which infractions of the law in regard to it are punished in Germany. In the city of Breslau the official charged with the duty of destroying a hog known to be trichinatous, neglected his duty, and in the meantime the owner of the animal slaughtered it and sold some of the meat before the fact was detected by the authorities and the balance seized. Several of those who purchased the meat succumbed to trichinosis, and the authorities proceeded against the owner of the animal, his wife and the functionaries of the city. The first two were condemned to fifteen years of hard labor and ten years' additional loss of civil rights and to perpetual surveillance of the police. The burgomeister was fined 60 marks and deposed. A circular was issued and sent to all provincial magistrates calling attention to the affair, and imposing on them the necessity of the keenest watchfulness against a possible recurrence of a similar affair. In the United States the owner of the meat would have sued the authorities for the meat that was seized, and for damages for interfering with his enterprise.—*National Druggist*, March 15, 1890.

Afraid of Leprosy.

A communication from the California State Board of Health was read at the recent Sanitary Convention at Norristown, Pa., urging legislation to prevent the importation of cases of leprosy or of persons specially liable to develop the disease. The communication was followed by a resolution of the American Public Health Association urging that all quarantine officials, to prevent the introduction of leprosy, exercise the same vigilance as they do in reference to yellow fever or cholera.

Secretary Lee announced that the Surgeon-General of the Marine Hospital Service had ordered that cases of leprosy arriving in the United States must be quarantined and returned.

NEWS.

—Dr. W. H. Byford, one of the most prominent physicians in Chicago, died May 21 of heart trouble.

—Cerebro-spinal meningitis is reported as prevailing to an alarming extent among horses in Kentucky.

—The Connecticut State Medical Society will hold its annual meeting in New Haven, May 28, 29 and 30, 1890.

—The State Medical Society of Pennsylvania will hold its fortieth annual session in Pittsburgh, June 10–13, 1890.

—A polyclinic, or medical institute, similar to the polyclinic at Vienna and Berlin, has been opened in Paris.

—The College of Medicine of Southern California held its annual commencement on April 16, 1890, and graduated a class of 7.

—The thirty-seventh annual session of the North Carolina Medical Society was held at Oxford, N. C., May 27, 28 and 29, 1890.

—Plans have been approved for the first of a series of buildings for the Pennsylvania Institution for the Deaf and Dumb at Mount Airy, Philadelphia.

—The French Minister of Marine has absolutely prohibited the medical officers of the navy from practicing hypnotism "under any pretext whatever."

—Dr. F. N. Otis has been appointed Professor Emeritus of Genito-Urinary and Venereal Diseases at the College of Physicians and Surgeons, New York.

—The attendance at the forthcoming International Congress at Berlin, this summer, is estimated to exceed five thousand, and special arrangements will be made in consequence.

—Joseph Hill, colored, who pleaded guilty to a charge of practicing medicine without being registered as a physician, was sentenced in Philadelphia, May 19, to six months' imprisonment.

—Dr. Holmes Judd died in Alton, Illinois, May 20, aged 70 years. He was the founder of the St. Louis Dental College, and, at the time of his death, President of the Illinois State Dental Association.

—There is a leper isolated in the City Hospital of Evansville, Ind. The patient is a man twenty-five years old and states he has had the disease for fifteen years. He has passed his life in several States, but has never been outside of America. The disease is of the tuberculo-anæsthetic form.

—A committee, consisting of Professors Moleschott, Corradi, Cocconi, Guareschi, and Vitali, and Signori De Cesaris and Tacconis, Doctors of Pharmacy, which was charged some time ago with the revision of the Italian Pharmacopœia, has almost completed its task. The revision has occupied twelve years.

—A young doctor of Vienna recently offended a Croatian girl, nineteen years old, and refused to apologize for his conduct. The girl thereupon challenged him to a duel, and on May 21 the pair fought in a room which had been hired for the purpose. The girl, who was educated in South America, and who is a splendid fencer, twice wounded the doctor, herself escaping unscathed.

—On May 19, the United States Supreme Court rendered an opinion holding to be unconstitutional the law of Minnesota requiring that all fresh meats sold in the State "shall be cut from animals slaughtered within the State and inspected 24 hours before slaughter." The case is entitled "State of Minnesota against Henry D. Barber," and is of great interest to dressed beef men, who win the case.

—Lieutenant-Colonel Charles A. Aden and Major John S. Billings, surgeons, have been ordered to proceed to Berlin, Germany, as delegates to the International Medical Congress. Major Billings is also ordered to visit afterwards, on official business, such points in Great Britain, France, Italy, Germany, Belgium, Holland and elsewhere as may be deemed necessary by the Surgeon-General of the Army.

OBITUARY.

DR. DANIEL P. MOYER.

Dr. Daniel P. Moyer, a very able and prominent physician of Bucks county, died at his residence in Doylestown, on Sunday evening, May 11. Dr. Moyer was born in Montgomery county in 1847, and was graduated from the University of Pennsylvania in 1872. Immediately after graduating he located at Dublin, in Bucks county, and soon, by his ability and exemplary character, built up a very extensive practice. Finding his health failing, he relinquished his practice here and moved to Doylestown this spring. Dr. Moyer's death was due to a severe attack of typhoid fever. He left a wife and four children to mourn his demise.

CLINICAL LECTURE.

QUINSY. — PERICARDITIS COMPLICATING CHRONIC BRIGHT'S DISEASE.—EXHAUSTION FROM EXPOSURE AND CARDIAC DISEASE.[1]

BY JAMES TYSON, M. D.,

LATE PHYSICIAN TO THE PHILADELPHIA HOSPITAL; PROFESSOR OF CLINICAL MEDICINE, UNIVERSITY OF PENNSYLVANIA.

Quinsy.

Gentlemen: The first disease I have to illustrate this morning is a very simple one, and yet one of great practical importance. The case is one of ordinary tonsillitis, or quinsy. The man's history is simple. He had his feet wet on November 27. The next day he was seized with a mild chill, and his throat on both sides became swollen and tender. He experienced great difficulty in eating and swallowing, and there was even at first obstruction in breathing. He had no chill after the initial one. This is the typical history of tonsillitis, a disease most easy of diagnosis.

It is with especial reference to the treatment, therefore, that I bring him before you, for I know of no simple disease in the treatment of which one may be more embarrassed than this.

Tonsillitis is an inflammation of the tonsil glands, usually terminating in suppuration. It is also called quinsy, although this term is sometimes restricted to the suppurating form. The most important question to decide, when called to a case of tonsillitis, is whether it is going to gather immediately, because the decision must influence the treatment. It is, however, a question not always easy to answer, and to say whether we shall use remedies to prevent suppuration, or to favor it. Very often for three or four days we will

[1] Delivered at the Philadelphia Hospital.

use means to prevent suppuration, only to see an abscess form in spite of what has been done. Again, at times, it is exceedingly difficult to know whether pus has actually formed. The duration of the disease is so uncertain under any circumstances that it is well to make an exceedingly guarded prognosis, telling the patient that ten days may elapse before a culmination is reached. While the prognosis is almost invariably ultimately favorable, it has happened that, in consequence of an involvement of both tonsils, the patient has been suffocated; and cases, though rare, have occurred where the sudden breaking of a tonsil abscess has caused death from suffocation.

Now as regards treatment. If we see the patient very soon after the chill it is reasonable to expect that antiphlogistic measures may cut the inflammation short. Among the best means for this purpose are pieces of ice placed in the mouth more or less constantly, and in addition to this, ice bags to the angle of the jaw. It may be desirable to satisfy the patient to use gargles, but I doubt whether they are useful. It is also doubtful whether the usual astringent solutions, such as silver nitrate, tannic acid and the like, are of value; but they may be used in the early stages. More efficient as a curative measure, and also useful to diminish tension and allay pain, is scarification. This may be followed by the local application of a four per cent. solution of cocaine, or a spray of the same, thrown into the throat, or cocaine may be used independent of scarification.

But are there any symptoms by which to determine a change of treatment from the antiphlogistic to that favoring suppuration? The recognition of fluctuation, of course; but this is not always easy. We may aid ourselves in this by putting the finger under the angle of the jaw, and pressing on the tonsil, and then, with another finger inside, make the touch. Sometimes it is difficult to get the mouth open wide enough to do this, but patience will generally accomplish it. Not infrequently the sense of fluctuation is obtained, and the bistoury plunged into the tonsil without result. It has happened that the internal carotid artery has been wounded in cutting a tonsil abscess, and it is accordingly recommended that the bistoury be guarded. But it takes a pretty deep cut to cause this accident. In other cases fluctuation is very evident, and not a very deep incision will bring out the pus, while scarification paves the way for the tonsil to relieve itself, as often happens.

A person having tonsillitis once is apt to have other attacks; and some people have quinsy every year. In the patient before us we have been able to abort the disease. Both tonsils were scarified, relieving the hyperemia, and the case has gone on to resolution. Usually four or five days limits the duration of a case of tonsillitis, but, as already mentioned, it may run on to ten days, and hence it is well to prepare the patient accordingly.

Pericarditis Complicating Chronic Bright's Disease.

I next present a patient who has Bright's disease, of what particular form does not concern us at present. But there is associated with it a complication quite common to this affection, namely, pericarditis. The patient is also almost blind from the presence of an albuminuric retinitis.

Pericarditis is secondary mainly to two diseases, acute rheumatism and Bright's disease. It also occurs in connection with pneumonia and pleurisy and with septic conditions, such as puerperal fever. Why this condition is favored by Bright's disease is not certainly known, nor do we certainly know how it is caused by rheumatism; but it is supposed that the poison, whatever it may be, which circulating with the blood causes rheumatism, acts also to produce the pericardial inflammation, which is favored by the friction of the surfaces. So the effete matters which soon accumulate in the blood in Bright's disease, are supposed to act similarly. In every case of Bright's disease, and of rheumatism, therefore, we should constantly examine the heart with a view to the recognition of this condition, and thus, while studying this case, we discovered a friction sound. These sounds are often of a very fleeting character, and will disappear in the course of a day. It was present yesterday; I will see if it be still here. It is still audible, but it is much less distinct than it was. It is a very low, soft rubbing, and has lost its "to and fro" character. It is not easy always to recognize a pericardial friction sound. The difficulty here would be even greater if we had not had the opportunity of recognizing it at a time when it was more distinct. There are several characteristics by which we distinguish it from cardiac murmurs; and yet it is often

mistaken for a valvular murmur, and *vice versa*. A characteristic friction sound, in the first place, is a to and fro sound, and while double in one sense, is not double like a double valvular murmur, as it has not the same relation to the systole and diastole. Secondly, it is a more superficial sound than a valvular murmur. Thirdly—although this is not constantly the case—it is apt to change its situation with a change in the position of the patient, the heart rolling from one side to the other. Fourthly, the character of the sounds are different. A friction sound is never blowing, whistling or piping, as is the valvular murmur, but when the valvular murmur approaches a soft, rubbing character, the resemblance is closer. A friction sound may be crepitating or creaking at times, depending upon the firmness of the lymph which is the cause of it.

Pericarditis is an inflammation of the pericardium with an exudation of lymph in the first stage, producing a roughness on the two surfaces of the pericardium, whence the friction sound. As this lymph is soft and gelatinous, or hard and rough, it gives a difference in the character of the sound. Very often our diagnosis of pericarditis is confirmed by the onset of the second stage, namely, the effusion of serum with a corresponding increase in the area of the heart's dulness; a dulness which is apt to be conical in shape. This dulness at first is associated with the friction sound. The obtuse apex of this dulness may be high up under the clavicle, while the point of highest dulness in health is at the fourth rib. In this case the dulness does not mount very high. It reaches only the third interspace. I am free to judge, therefore, that there is no pericardial effusion here. In order to settle the question further, I will look for the apex beat, and I find it most distinct in the line of the nipple, and below—outside of the normal position; this is due to a slight hypertrophy which is here present. Nor is there a trace of dulness at the apex.

Where a pericardial effusion exists, there is generally dyspnœa. The action of the heart becomes irregular and embarrassed. During the early stage of pericarditis, outside of the physical symptoms, very often there is nothing distinctive. The pain of the inflammation is very much less than in pleurisy, although the membranes are the same. There is pain and discomfort, however, to a certain extent. There is sometimes an associated pleurisy, and, it is claimed by some, that pain when present is due to this complication.

As regards treatment, the first thing to do is to put a blister over the heart at once, and follow this, or associate it, with measures to regulate the heart, such as digitalis. A blister in pericarditis gives excellent results. Almost immediately the patient becomes comfortable, the dyspnœa passes away and the physical signs disappear. We may prevent an effusion by its use. In rheumatic cases we should treat for the rheumatism as well, and similarly in Bright's disease. These cases almost always need stimulants.

These measures are, as a rule, efficient. Very rarely does a patient die from the effects of pericarditis. Sometimes it happens that the effusion increases to such an extent that unless prompt action is taken the patient will perish. Paracentesis of the pericardium must then be done in the fifth interspace, one inch to the left of the sternum, to avoid the artery which runs along the edge of the sternum. When there is pus in the pericardium it is absolutely necessary to tap, and a drainage-tube may even be inserted into the sac. Adhesion often takes place as the case recovers, the two surfaces becoming united as the effusion is removed. Complete adhesion is not favored by the constant movement of the heart, and bands of adhesion are therefore often seen. At times, however, the pericardial sac is fused into the visceral layer. In such cases with every beat of the heart one or more interspaces are drawn in, and this aids us in making the diagnosis of adhesions.

Exhaustion from Exposure and Cardiac Disease.

The third case I show you is an old man who says he is 102 years old; but I fear he is not correct as regards this. He is unable to talk our language, and I can get no history. When admitted on Saturday last, he was almost pulseless. Hot-water bags were placed to his feet. He had dropsy of the legs to a very positive degree. Listening over his heart, we found it very irregular, but could make out no murmur. We examined his urine and found it loaded with albumin. We concluded, therefore, that there was Bright's disease. This is a case which will demonstrate the value of comfort, warmth and rest. On Monday we examined his urine and found no albumin. His heart had steadied somewhat, but was still irregular.

To-day we recognized a systolic murmur. The heart, although much more regular than it was, is still very feeble. I wished to show you him particularly to illustrate the value of warmth and rest. The dropsy and albuminurea have disappeared, and the heart has become stronger, and I have no doubt the man will be about again. The necessity of caution in prognosis is also thus shown.

COMMUNICATIONS.

THE DIFFERENTIAL DIAGNOSIS AND TREATMENT OF THE CONTINUED FEVERS OF THE SOUTHERN STATES.[1]

BY B. F. HUMPHREYS, M. D.,

HAWKINS, TEXAS.

The monograph of Dr. W. W. Johnston "On the Geographical Distribution of Typhoid Fever in the United States—its relation to Fevers of Malarial Origin and to Obscure and Unclassified Forms of Continued Fevers," is a valuable contribution to this subject, inasmuch as it is a collective investigation reflecting the opinion of three hundred and fifty reputable physicians, chiefly Southern practitioners, whose views, for the most part, are based upon clinical experience. Although there seems to be much confusion, apparently due to a diversity of opinions existing in regard to the nature, classification and nomenclature of this group of fevers, there are, nevertheless, in these brief historical sketches, the outlines of the prevailing types of the continued fevers, indigenous to the Southern States.

Having elsewhere discussed this topic somewhat at length,[2] it seems unnecessary at present to enter into a long study of the nature, differential diagnosis and treatment of these fevers. But a *résumé* of some of the leading aspects which pertain to this subject may be of interest at this time. The geological conformation, latitude, climate and other characteristics of the Southern States, especially those bordering on the Gulf and Atlantic and those lying in the southern portion of the great valley of the Mississippi, naturally incline to the propagation of the continued fevers peculiar to these States. These fevers differ so materially from those which have long been recognized under a special nomenclature that has been almost universally adopted, it must be evident to all that the unclassified forms of these continued fevers, concerning which there has been so much misunderstanding, should receive the consideration which the importance of the subject seems to demand, by giving to each an individualized distinction and cognomen, or by referring them, as suggested by Prof. W. W. Johnston, to typhoid fever or to adynamic malarial fever.

Much confusion has existed in relation to the true nature of these continued fevers, which is probably due, in a measure at least, on the one hand to incorrect methods of investigation, and, on the other, to a proneness to classify them under a universally recognized nomenclature which is in no wise suited to the character of a fever, entitled perhaps to an individualized distinction. This is probably true as regards a certain type of continued fever prevalent in these States, which, for want of a more appropriate name, had frequently been designated under the neologistic term of "Typho-Malarial" fever, thereby usually nullifying the diagnosis and of necessity increasing the confusion.

The result of this seems to be, that any fever presenting symptoms resembling typhoid on the one hand and malarial fever on the other has usually been termed typho-malarial fever by the advocates of that theory. The diagnosis is therefore frequently made without observing the special restrictions necessary to justify such a classification—if, indeed, the term is worthy of further recognition and continuance. If so, then it must be conceded that it should be used only in the restricted sense the author of the term finally proposed that it might be applied: to those fevers which result from the combined influence of the causes of malarious fever and of typhoid fever.

The late Dr. Samuel M. Bemiss, in his monograph on typho-malarial fever, in *Pepper's System of Medicine*, while expressing the belief that the term might possibly be a convenient addition to medical nomenclature, insists upon restricting its use "to define a disease compounded of the two pathological factors, which when acting sep-

[1] Read before the American Medical Association, Nashville, Tenn., May 21, 1890.

[2] *Nashville Journal of Med. and Surg.*, March, June and December, 1885; March, June, July and September, 1886; *Therapeutic Gazette*, September, 1888; *Texas Courier-Record of Medicine*, February, 1889.

arately produce either typhoid or malarial fever." Professor Edward G. Janeway, as is well known, has also said that he did not believe it possible to admit the use of the term in any other sense than that adopted by Professor Flint in his *Practice of Medicine*, namely, as indicating the symptoms of malarial empoisonment to those of typhoid fever, with the effect of rendering the course of the disease peculiar, and he thinks it would have been wiser altogether to dispense with the term, and, under the head of typhoid fever, consider the malarial poison as capable of producing a considerable variation in the ordinary course of the disease.

Dr. Janeway's views, with reference to the irregularity which characterizes the use of the term (typho-malarial) are strongly corroborative of the opinions long held by Professor Robert Bartholow, who, from the first, as all the world knows, has opposed the adoption of this term in our nomenclature. Both of these distinguished clinicians have shown that the fever of typhoid is remittent in character, with a gradual rise during the first week of its course; that this same remittent character is seen in the latter part of the course of many typhoid cases; and that the occurrence of sepsis in the course of a typhoid fever will also produce an *apparent* malarial or *remitting* character to the fever. Reviewing his large clinical experience in New York City, Dr. Janeway assures us that it has happened extremely rarely that in a person dead of typhoid fever, evidences have been found at the autopsy proving the existence of malarial empoisonment.

It may be observed in reference to the restrictions implied and expressed in the use of the term typho-malarial, that the infrequency of typhoid fever in Southern latitudes, especially in the rural districts and in malarious regions, is a well-known fact which seems to controvert the probability, and even the possibility of the existence of so many cases which are diagnosticated typho-malarial fever, for the typhoid factor evidently is not present as frequently; and, if it were, it could not perhaps be as far diverted from its wonted course by any complication having the power to prevent the manifestation of the positive and recognized symptoms and lesions by which the disease is diagnosticated without reference to any complications. As I have elsewhere observed, it yet remains to be proven that the difference sometimes observed in the appearance of the ulcers in Peyer's patches is due, as has been claimed, to the combined operation of the malarial and the typhoid poison, producing a special character of ulcers pathognomonic of typho-malarial fever, so-called. If any such evidence could be uniformly produced from subjects who die of this fever, and if it could be demonstrated that the intestinal lesions differ from the *plaques molles*, or the *plaques dures* of typhoid, then the morbid anatomy might be regarded as affording some proof of a distinct or special type of fever, and thus furnish the basis for the differential diagnosis between it and typhoid fever. Until this is done, however, the characteristic intestinal lesions and other symptoms of enteric fever must still be regarded as the old and correct landmarks of typhoid fever, whatever complications may intervene.

The typhoid fever of this State, as generally seen, seems to be divested of many of its characteristic symptoms; wherefore it has been claimed by many of our physicians who have seen the disease as manifested in the more northern latitudes, that there is no true typhoid fever in this State. The fever termed "typhoid" possesses some of the characteristic symptoms —enough to justify the diagnosis. There is in this fever rarely the pronounced delirium common to it in higher latitudes; there is, however, a pseudo-somnolence, with a clouded mind; there are manifest symptoms of tenderness, pain and gurgling in the right iliac region; tympanitis; occasionally intestinal hemorrhage, and even perforation; the eruption of rose-colored spots is not constant; usually there is diarrhœa, but it does not seem to me that it is as characteristic as it is in the classic type of the disease. The fever, as generally seen here, might be termed a typical typhoid.

The excellent contribution of Dr. R. D. Maury, of Memphis, Tennessee, on "Malarial Continued Fever" (*American Journal of the Medical Sciences*, April, 1881), is an accurate pen-picture of a common type of continued fever which prevails in the Southern region of the Mississippi Valley. It is also quite prevalent in a large portion of this State, and probably to some extent throughout the southern portion of the United States. This is the form of continued fever, more than any other, perhaps, which has been termed typho-malarial, without any sufficient reasons for such an application of the term.

The symptoms of this fever, as detailed elsewhere, do not justify the use of the term, for they are very like those of typhoid fever, —in fact, there is rarely, if ever, a typical symptom present. In this type of continued fever, the cerebral symptoms alone seem quite sufficient to make a differential diagnosis between it and typhoid fever. The mind of the patient, as a rule, is unclouded, he being rather alert than otherwise. The patient manifests much anxiety and concern with reference to his condition; notes the arrival and departure of visitors, with whom he converses cheerfully much of the time, and not infrequently he desires to read a book or paper, especially during the morning hours. He rarely, if ever, has any of those illusions peculiar to typhoid fever.

But there are other points of difference between these fevers, which are worthy of note. There is in continued malarial fever a conspicuous absence of the characteristic symptoms of typhoid fever, and in their place is the unmistakable evidence of malarial empoisonment; although not so pronounced as in malarial remittents, it is nevertheless easily recognized. Periodicity here, as in other forms of malarial fever, is plainly manifested in the diurnal cold stage, which is invariably followed by an elevation of temperature. The cold stage may amount to a chill or rigor, but usually there is nothing more than a slight coolness of the feet and hands, the tip of the nose and the ears, the patient either covering himself more closely or calling for additional clothing. In other cases the cold stage is not so easily recognized. The morning temperature in mild cases is usually 101° to 102° F., in the evening 102° to 103½° F. In violent attacks, which are due probably to sepsis, the morning temperature ranges from 103° to 104° F., the evening pyrexia may be 105° or 106° F. Generally, however, the temperature does not exceed 104° F. There is usually a defervescence of the fever about the end of the third week, although it may continue much longer, generally terminating at or near a septenary period. The long-continued cases usually present adynamic symptoms.

As observed by Dr. Maury, "this fever presents a stadium of increase of about one week, a stadium of height of five or six days, and a stadium of decrease which terminates completely on the twenty-first day. . . . Constipation and a concave abdomen are marked features. All the essential features of typhoid or enteric fever are absent. No diarrhœa, no ilio-local tenderness or gurgling, no meteorism, no eruption of rose-colored spots. . . . It begins, continues and ends as a continued fever. . . . Its duration is no way affected by the exhibition of anti-periodic medicines."

In view of the foregoing facts and outlines, it seems strange indeed that any one would apply to this fever such a term as typhoid-malarial. There is not, in fact, even a shadow on which to base the diagnosis of typhoid.

But in the typical forms of typhoid fever, which are also common to the Southern States, the possibility of making an erroneous diagnosis is even greater than in the other forms of continued fever. The atypical forms of typhoid in tropical and subtropical regions—although not so common as the adynamic type of malarial fever already referred to—may mislead us in the diagnosis; for here there are some symptoms of typhoid on the one hand and a resemblance of malaria on the other; but a rigid and cautious investigation will enable us to establish a correct diagnosis even in the presence of complications. Quain observes that in India cases of enteric fever have been, and are, mistaken for malarial intermittent. He says: "There are cases of a mixed nature in which a thread of malaria, so to speak, runs through the symptoms and obscures them;" and, further, that "the term typho-malarial has come into use there to distinguish these cases." From which it appears that the symptoms of enteric fever there, as in other regions with similar environments, may be obscured by "a thread of malaria," thereby producing some variation of the ordinary course of a typhoid fever, as Professors Bartholow and Janeway have already observed. But it does not appear that the adoption of the term typho-malarial in India has helped them out of their confusion or that it has enabled them to avoid the mistakes to which the distinguished lexicographer refers. Indeed it seems that the term there, as elsewhere, only adds to the existing confusion. Dr. Johnston, in his paper already referred to, very truly observes: "As at present employed, the term typho-malarial has no determined meaning, leads to confusion and misunderstanding, is a cover for uncertainty and ignorance and should be discouraged and abandoned."

It may be observed in this connection that some of the most distinguished clini-

cians of other countries have also investigated this subject somewhat carefully. Dr. Edward Squire, of London, has given us an interesting and unique monograph, from his standpoint, relating to this topic. (*American Journal of the Medical Sciences*, April, 1887.) Dr. Squire, it may be remarked, was a medical officer in the British Army at Suakim, on the Red Sea, during the recent English campaign in Egypt, "where seemingly occurred the same forms of malarial disease that are met with elsewhere," as Dr. H. K. Leake has observed in an editorial review of the above paper (*Texas Courier-Record of Medicine*, July, 1887). To Dr. Squire's large clinical experience, in London and the English army, is added his collective investigation on this subject, contributed by many of the most eminent physicians of the English realm, including medical officers of the army and navy. Having reviewed the individual expressions and opinions of this reputable class of physicians, in connection with his own observations, Dr. Squire gives expression to the opinion held by the Commissioner of Inquiry concerning the disease as it prevailed in the United States army during the war between the States—resulting in the conclusion that the so-called typho-malarial fever was "bilious remittent fever, which, having not been controlled in the primary stage, had assumed that adynamic type which is present in enteric fever," from which Dr. Squire formulates the following definitions: "Typho-malarial fever is a malarial fever which has assumed that adynamic type which is present in enteric fever." He says the medical officers of the army support him in this definition; although Fleet Surgeon Norbury, while admitting that the symptoms of enteric fever may be modified by malaria, says: "The so-called typho-malarial fever is simply enteric fever and nothing else." From which it may be inferred that the cases which came under the observation of Surgeon Norbury were probably atypical forms of typhoid fever not very unlike those, observed elsewhere and designated as typho-malarial fever. But admitting that such cases should properly be referred to the typhoid group, the definition of Surgeon Norbury is not one of universal applicability, for it cannot include a large class of continued fevers of tropical and sub-tropical latitudes, where they are so frequently and erroneously classed as typho-malarial, without the enteric pathology noted by Norbury. To this latter class of fevers, Dr. Squire's definition seems applicable.

Simple continued fever, as commonly observed in this State, is a fever of more gravity and of longer duration than is ascribed to this form of fever in the text-books on practical medicine. It is a fever of a mild and negative character, without any of the special symptoms of typhoid or malarial fever and its course cannot be abridged by specific (quinine) treatment. It may not continue longer than from twelve to fourteen days, but sometimes it lasts longer—from eighteen or twenty to forty days, or even more. More frequently than otherwise, the fever subsides by the end of the second or third week. I have occasionally seen cases of this fever continue forty days, and, during all that time, the patient never went to bed, except at intervals during the day to rest himself. Usually, however, the subjects of this fever are unable to leave their beds, where a portion of the time is spent in conversation with visitors, and occasionally half an hour in light reading. The temperature rarely exceeds 103½° or 104° F., and much of the time it ranges between 101° and 102½° F. There is no distinctly marked periodicity or other characteristic evidence of malarial empoisonment. Usually it occurs during the heated summer season, or later on, just after a long, dry, hot summer, during which there has been very little manifestation of malarial fevers. Indeed it has seemed to me that in this fever, or in the graver forms of it at least, there is a striking resemblance to that type of fever designated as "thermic," so graphically described by Professor Horatio C. Wood and Professor John Guitéras, formerly of the United States Marine Hospital Service. As observed elsewhere, the pathogenesis of this type of fever is imperfectly understood, but it seems quite probable that the long-continued and excessive heat of tropical latitudes and adjacent regions may be capable of producing, not only in feeble and over-worked persons, but possibly in some constitutions apparently robust, a depression, exhaustion or more or less pronounced paresis of the inhibitory apparatus of the heat functions, thereby impairing the normal equilibrium between heat production and heat dissipation.

Dr. Maclagan in the Clinical Society of London (*Lancet*, March 31, 1888) maintained "that the metabolism of the tissues is interfered with through the nervous sys-

tem, there being a kind of paralysis of the inhibition which normally keeps the tissue changes within bounds, and that the resistance or inhibition of the heat-centres being removed, hyperpyrexia results." These expressions of opinion seem to be in accord with the theory of thermic fever, so ably maintained by Drs. Wood and Guitéras.

In view of the fact that the inherent tendency of the physiological functions is to resist any extraneous influence that may be capable of perverting the intrinsic or natural order and harmony essential to the "eternal fitness of things," it follows, as a matter of course, that the same cause, acting against greater resistance, may produce a fever of less intensity and continuity—one having a comparatively mild pyrexia—which is, indeed, the usual character of this type of fever. At least, such is its nature as manifested in this latitude.

Treatment seems to have but little, if any influence on the natural course of this type of fever, and about all that is necessary is to render the patient as comfortable as possible, administering such remedies as may be indicated, and cautiously avoiding unnecessary drugging, which interferes with the well-being of the patient. When the fever produces much discomfort and restlessness, a suitable dose of antipyrin or phenacetin, or some other mild sedative and antipyretic, may be given and repeated as often as necessary. To support the failing strength, a nutritious, easily-assimilated diet—not altogether nor always liquid—is our main reliance. Diuretics and aperients seem useful. Wine, brandy and other alcoholic stimulants appear to be beneficial in many of these cases, especially if supplemented with tonic doses of quinine, which seems to be useful in sustaining the capillary circulation. Two or three grains of quinine, every four hours, may be given to an adult with apparent benefit. Insomnia is sometimes troublesome. This is relieved by means of chloral, bromidia, sulphonal, or an opiate—the two first having the preference.

The diagnosis of any type of continued fever is seldom made and confirmed until the fever has run on in the even tenor of its way for several days or a week, unchecked by the repeated and persistent exhibition of antiperiodic remedies. By this time, if not sooner, we are driven to the conclusion, albeit reluctantly, that we have a special type of continued fever to deal with, instead of a mild, abortive remittent, as we had at first supposed and hoped. The first administration of quinine, in daily antiperiodic doses, with the view of checking the natural course of the fever, seems to be not only useless but positively detrimental to the well-being of the patient, and proves to be "a disturbing element," as Dr. Maury has truly remarked.

I have recently observed in reference to "The Use and Abuse of the New Antipyretics" (*Texas Courier-Record of Medicine*, April, 1890), it is not at all probable that any of these new antipyretics will ever supplant quinine—the old reliable antipyretic and antiperiodic in malarial fevers. By this I do not mean to say that quinine is a rival of the modern antipyretics; for it is not. But all of us, I suppose, have seen low forms of malarial remittent fever in which the vital powers were so overwhelmed with the effects of the disease, that we would not dare to administer antipyretics or depressing medicaments of any kind; for we have learned by experience, if not by precept, that nothing except quinine to cinchonism will relieve such patients, thereby demonstrating in such conditions its unrivalled properties as not only an antiperiodic, but a special and safe antipyretic as well.

As to the treatment of continued malarial fever, it may be remarked that the remedies usually administered in simple remittent fever, or quinine at least, will probably have been given before the physician is called. If such remedies have not been properly administered, they should be resorted to at once and fairly tested, with the view of arresting the fever, if possible; for it is widely believed that simple remittent fever not infrequently assumes a continued character through neglect or inefficient treatment at the outset; and careful observations seem to confirm this opinion. After these preliminary remedies, the treatment outlined for simple continued fever will usually prove satisfactory.

In the graver forms of the disease, dangerous symptoms are to be treated as they arise. The hepatic, digestive, renal and cutaneous functions require constant attention—never over-stimulating them and never permitting them to become suspended for any considerable length of time, which would evidently intensify and prolong the fever beyond its natural course and duration. All nervous disturbances should receive prompt attention. Here antipyrin and phenacetin seem to be exceedingly

useful. Hyperpyrexia, if due to sepsis, calls for antiseptic remedies. The hyposulphite of soda, eucalyptus, baptisia and "Bartholow's mixture" are all apparently useful in this condition. In some cases the hyperpyrexia seems to be the result of accumulated and intensified malarial influence. When this is the case, moderate cinchonism appears to be quite beneficial, reducing the temperature to a degree of tolerance and safety.

Much depends upon the proper nourishment of the patient, for, if this be neglected, medical treatment, however rational, will most probably prove a failure, as the fever will continue far beyond its natural duration, or the patient will succumb to the combined influence of the fever and inanition.

THE FEEDING OF INFANTS.[1]

BY HENRY L. COIT, M. D.,

NEWARK, N. J.

The unretarded growth of the infant during the first year of its independent life is beset with difficulties which hitherto have well-nigh baffled the efforts of physicians. Of the four thousand deaths occurring in Newark, N. J., last year, more than twenty-five per cent. were of children under the age of one year; being about one-fifth of all who were born.

This enormous mortality, which exceeds that of any other period of life, is suggestive of sad defects in our knowledge of the means for the care and protection of the young. These facts are a greater reflection upon our intelligence, when we consider that among none of the lower mammals do we find the young dying in such large numbers.

In the mind of the profession at large there is a wide diversity of opinion concerning the methods to be employed in the dietic management of children at this early period of life. So vague and contrary are the views held on this subject, that even scientific observers, who agree on other points, are at variance in regard to it.

We find, also, that the subject of infant feeding is viewed from different standpoints, not only by physicians, but by the chemist, the dairyman, and the mother; and it is not strange, therefore, that the physician should find himself in conflict with one or another of these, who, by reason of their limited knowledge, fail to apprehend the truths which lie beyond the range of their immediate vision.

This general want of agreement on a question of such vital importance, is a sufficient warrant for any attempt to harmonize the discordant elements; and also for any effort to establish a more rational basis for our methods.

Nature has provided a food for the first year of human life, in the normal secretion of the mother's breast; and in a manner which renders it impossible to improve either the food or the method of feeding. It is perfect in its composition, digestibility and temperature; and if it is true that nature makes no mistakes, except as we pervert her laws and turn aside her efforts in wrong channels, then it would follow, that where physical health exists in the mother, the lacteal secretion will always agree with her child, and conduce to the most perfect development.

In studying the composition of woman's milk, it is important to bear in mind some of the principles of nutrition. Bodily growth or repair in the adult seems to maintain an even balance with the destructive waste of oxidation; with advancing age this equilibrium is lost, because of weakened assimilation, and consequent mal-nutrition. In the infant, on the other hand, an entirely different state of things exists: here we find a maximum of activity in the digestive and assimilative functions, with a minimum of waste, so that we have increased and rapid development.

In woman's milk are found all the elements of the more highly organized vegetable and animal foods: the proteids, which are the casein and albumin; the carbohydrates, which are supplied in the lactose; the fats, which are the most complicated constituents of milk; the mineral salts and water. In estimating the relative importance of these principles it is well to know that the dynamic value, which is manifested through nerve force and involuntary vital action, is generated from the proteids and fats; that the calorific properties, which regulate the thermal units of the body, reside in and result from the decomposition of the carbohydrates; and that the albuminoids also are supposed to have an intimate relation to the formation of adipose tissue.

Many chemists have undertaken the analy-

[1] Read at a meeting of The Practitioners' Club, Newark, N. J.

sis of human milk, and there are many differences in their results; the subject is one around which there are many difficulties, especially in the determination of the albuminoids and fats. Dr. Arthur V. Meigs, of Philadelphia, has written a long monograph defending the statement that woman's milk contains only about one per cent. of casein, whereas Professor Leeds finds a much higher percentage, namely, from two to three. Foreign chemists have generally reported from three to five per cent. of these principles. These differences are probably due to the imperfect methods of determination. I am of the opinion that casein in woman's milk is not a constant quantity during the whole period of lactation, and I am supported in this view by the experimental observations of Simon, who, after making many exhaustive analyses of woman's milk at different periods of lactation, concludes: first, that the quantity of casein is at its minimum at the commencement; it then rises considerably and ultimately attains a fixed proportion in the later part of lactation. My own observations have led me to believe that since the proteids are important factors in the early development of the child, nature provides these compounds in a proportion exactly suited to the peptic power of the child's stomach; just as the full digestive capacity is supplied with other constituents of the food. In this connection I would call attention to the fact that several years ago Dr. Henry A. Mott, of New York, during the analysis of many samples of milk from Caucasian and African women, found that in the latter the albuminoids were uniformly in excess, and in this respect as well as in the other features of specific gravity, color and general appearance, resembled cow's milk.

In fat principles the average woman's milk is not widely different from cow's milk, containing as it does about four per cent. of fat, which, however, consists chiefly of the more stable fatty compounds, namely, olein, palmatin and stearin; together with these are found a very small percentage of the volatile fatty compounds, among which are butyrin, caproin, etc. This minimum of volatile fats in human milk is due to a mixed diet, whereas milk of the lower animals, which are exclusively herbivorous, yield a lower percentage of the unstable and deleterious principles, which accounts for the distinctly acid reaction of such milk.

In woman's milk we find a much higher percentage of carbohydrates than is found in that of the lower animals, except perhaps the mare or goat. Chemists are generally agreed that seven per cent. represents the average quantity, which is reasonably constant. This principle, lactose, being a sugar of animal origin, has some distinctive properties. In the stomach a portion of it is readily changed into lactic acid, which plays an important part in the digestion of the albuminoids; this is well to remember when we have to use sugar in a food mixture. Unlike cane sugar, milk sugar does not readily take on the alcoholic or the butyric fermentation. Of the mineral salts and water nothing need be said except that both are necessary to the building of the tissues, and, being inorganic compounds, are not liable to change.

It would seem unnecessary to defend this common food for infants; and yet we are forced to do this by the fact that a large proportion of the mothers of to-day are either unable or unwilling to nourish their young. Among the causes which have determined this unfortunate condition of the race are, the injurious effects of modern social life, and a desire to escape responsibility and trouble; yet it is safe to assume that this deplorable state of things would not exist, at least not to so great an extent, had not the confidence of the public and a large part of the profession, been established in the numerous manufactured substitutes for mother's milk. The nursing-bottle was once unknown, and that within the recollection of most of those who now use them. Until within a few years this expedient was regarded simply as an economical substitute for the foster-mother; but now both she and the natural mother are relegated to other fields of action.

In judging of the merits or demerits of substitute foods, new combinations of which are brought daily to our doors, it might be well to lay down a principle to guide us, namely: Any food for infants under one year old, that departs in constitution from the character and proportion of proximate elements found in woman's milk, is not only to be regarded with suspicion, but discarded as likely to be detrimental to the child, and will in all probability defeat the purposes of nutrition.

We are indebted to Dr. T. M. Rotch, of Boston, for an exhaustive treatise on manufactured infant foods, in his valuable article on infant feeding in Keating's encyclopædia.

Here we are told that almost every manufacturer has made claims which he cannot substantiate, and after a careful and impartial study of their analyses we find in them all, without exception, faults, either in the percentage of essential ingredients, or in the addition of foreign substances which were never designed for the infant's stomach. The apparent success of some of these preparations has been due in part to advertising; but largely, I think, to a general misapprehension of the causes of failure with cow's milk. It is a common practice when cow's milk does not agree on the first trial, to resort at once to a patent mixture, and then in the event of failure, to change from one to another in sheer despair, until finally the infant, if not already dead, is imperfectly nourished and enters childhood with weakened digestive powers.

Cow's milk has been used as a substitute for mother's milk from the time when it first became necessary to nourish infants by hand. That this substance is the one best adapted to our purpose is conceded by all but a remnant of the profession, and yet the fact that very many physicians recommend patented mixtures is evidence that in resorting to these expedients they have not intelligently studied the relations of cow's milk to the infant's digestion.

In order best to understand the causes of failure, we will consider the comparative composition of woman's and cow's milk. The gross quantitative analysis will teach us much in this direction. The total solids are about the same in each, namely, twelve per cent., so that the difference lies in the unequal proportions of the same ingredients. The following table of percentages will show approximately how average cow's milk may be brought by synthetical adjustment to correspond to woman's milk:

Woman's Milk.		Cow's Milk.	
Casein	2	Casein	4
Milk Fat	4	Milk Fat	4
Milk Sugar	7	Milk Sugar	4
Water and Salts	87	Water and Salts	88

Modified Cow's Milk.

Cow's Milk + equal bulk spring water	= 2	Casein 2 Milk Fat 2 Milk Sugar 2 Water 94

If to half of this we add

Milk Fat 2 Milk Sugar 5	we will obtain almost exactly	Casein 2 Milk Fat 4 Milk Sugar 7 Water and Salts 87

We find then that cow's milk contains twice as much casein as woman's milk, and on the other hand woman's milk contains nearly twice as much sugar as cow's milk, the fat being about the same in each. Judging from these differences, it is apparent that ill success with the latter milk is largely due to our failure to adjust the disproportion in its several constituents.

The sources of cow's milk, and the dangers through which it passes in being brought to us, are divisions of this subject too large to be fully treated in this paper. Strict sanitary control of the milk supply will be necessary before we shall remove these sources of danger, and before we may hope to improve the present defective dairy-farming.

Among the disadvantages in the use of cow's milk are its contaminations. First, we have the transmitted foreign matters, such as the tubercle bacillus, which, according to Ernst, may be brought to us from cows which have no localized tubercular deposits in the udder; notwithstanding the fact that absence of local disease has been supposed by Koch and others to render the milk inocuous. This fact alone would justify the sterilization of all milk given to infants. Then we find the bacteria which determine the various fermentations and the putrefaction of milk, which are inevitable in all milk that is exposed to the air, and only await the favorable external conditions to spoil it. We have also the typhoid bacillus, found in milk which has been carried in containers washed with contaminated well water. There are also, in much of the cow's milk, abnormal constituents in the excess of volatile fatty compounds, which are easily changed into acids; chief among these is caproic acid, which is produced, together with other volatile acids of the fatty series, by the oxidation of albuminous substances used for food. We find beside these, various chemicals which are added for commercial purposes, such as the nitrates, used to destroy the garlicky odor of a turnip diet, and which produces in milk a chemical compound isomeric with nitroglycerin. Water is the least dangerous of all injurious additions, unless it be added indirectly, by feeding cows so as to increase their thirst and consequently their milking capacity. Milk so watered has a low specific gravity and carries with it deleterious principles.

Poisonous substances are found in milk which has been improperly handled; of these tyrotoxicon is best known, being described by Vaughan. It is a poisonous ptomaine

occurring in milk which has been allowed to stand long in an excessively acid condition. There is, no doubt, some causative relation between the improper feeding of cows and this poison. If a diet rich in albumin and devoid of starch (beer-grains) produces an increase in the fatty acids, and by the development of "bacillus proteus" rapid putrefactive changes are determined, it is highly probable that poisonous ptomaines would be produced.

There are small dairies in the suburbs of the larger towns and cities, where an almost exclusive diet of beer-grains is used, and the milk thus produced is sold to small consumers. The present low price paid by middlemen to the producer, namely, one and a half to two cents per quart, renders it imperative that the latter should find cheap food for his cattle, that which will determine the largest output of milk. Thus, resource is had to brewery waste, cheap roots, etc., instead of the solid grains of feed, with clover and timothy hay for fodder.

Beer-grain is, perhaps, more generally used than any other of the cheap foods. If the dairy district happens to be at a distance from a brewery, some of the farmers store it in earth cellars for the winter; this storage is begun in June when the price reaches the low figure of three dollars per ton. Being a waste by-product in the manufacture of ale and beer, it consists chiefly of the gluten of the barley, with its cellulose. The seventy per cent. of starch, sugar, dextrin, etc., have been removed, leaving nothing of a nutritive value but the thirteen per cent. of proteids. It is wet when sold, easily undergoes fermentation, and is often given to cows in this condition. Town dairymen obtain it fresh, but this advantage is offset by the larger quantities used. It is the testimony of the better class of dairymen that the feeding of this refuse destroys the cows' digestion in about seven years, and renders them unfit for further milking.

It is fortunate, however, that reliable sources of milk are not wanting; I have frequently examined samples of milk from reputable dairies in our own State, at a time of year when pasture was no longer to be had; and I have always found them above the standards of purity as set by health boards. Such sources should be diligently sought and encouraged.

The old method of diluting cow's milk with water, and gradually increasing the milk with the advancing age of the infant, from one-third to two-thirds, is familiar to every physician. The defects of this mixture are evident in the shortage of sugar and the low percentage of fat. Dr. William Pepper has long added cream to this diluted milk, with from five to six drachms of sugar of milk to the pint; boiling the mixture when found to disagree. The labors of Dr. Arthur V. Meigs have resulted in great advance in our knowledge of this subject. His experimental observations and clinical experience combine to command the attention of every thoughtful physician; nevertheless, his claim that mother's milk does not (and, consequently, any mixture should not) contain more than about one per cent. of casein, is accepted with varying degrees of confidence by the profession. While my own experimental observations have been limited, yet by my clinical experience I am forced to the conclusion that this estimate is too low; except it be in the early part of lactation. My own practice has been, when a milk mixture was required, to gradually increase the albuminoids to the maximum of the infant's peptic power, and I am convinced that I have thus obtained more efficient nerve power, more vigorous nutrition and a greater resistance to disease, than where mixtures containing only one per cent. of casein were employed without change.

Various mixtures have been devised from time to time with cow's milk as a base; but it remained for Dr. J. F. Meigs to add cream and milk sugar to diluted and alkalinized cow's milk, with the object of adjusting the proportions to correspond to that of the woman. The mixture resulting from his practical experience, and perfected later by Dr. A. V. Meigs, has been on trial for several years. There can be but little objection to this combination on the ground of faulty constitution, but we have found some difficulties in the way of its practicability. The cream to be added is supposed to contain a definite percentage of fat, namely, from fourteen to sixteen. In the country, it would be difficult to determine for many cases the amount of fat contained in a given sample of cream; and in the cities it is not easy to obtain cream at any price. The milkmen object when asked to bring it, on the ground that they do not skim their milk, and when it is obtainable from them it has a varying and always unknown percentage of fat. Another, though minor, objection to the above mixture, is its distinct alkalinity. In my judgment twenty-five per cent.

of lime water is too much. This quantity would only be called for when using a distinctly acid milk, such as is sometimes sold; but when the milk is brought from cows which are properly fed it is not nearly so acid and does not require this treatment.

The recommended mixture of Dr. T. M. Rotch, which is constructed on the same plan as the Meigs' mixture, is open to the same criticism so far as the cream is concerned. The twenty per cent. centrifugal cream of this author which may be obtained in cities is not easy to get in other quarters.

The mode of measuring the sugar in both of these mixures is often found impracticable, in that the quantity required is determined with a measure of weight.

Meigs' modified mixture, suggested at the recent meeting of the American Pediatric Society, is intended to simplify the work of preparation, and it does this effectually. Fresh milk is allowed to stand in a tall vessel for three hours. The top half containing cream is poured off and put aside for use. Sugar water is made by dissolving eighteen drachms of milk sugar in a pint of water. In preparing a four-ounce feeding, three tablespoonfuls each of the top milk and lime water are mixed together, and to this is added two tablespoonfuls of sugar water. It might be urged as an objection, that the mode of adjusting the fat in this mixture is somewhat uncertain. The raising of cream is determined by several variable conditions, and I think three hours is hardly sufficient time to allow all the fat to collect in the upper portion of milk when placed in a tall vessel. However, this mixture is of great utility. I have found it very useful when beginning the proper treatment of ill-fed infants, where a more perfect adjustment could not be carried out.

As milk is the only food which may be taken with advantage during the greater part of the first year, and since in this period the average infant will consume nearly five hundred quarts, it becomes important that we should lay hold of every expedient designed to aid us in perfecting our methods of preparation. The conditions required in order that we may reach this desideratum, are,

First. The uniform purity of materials and the ability to obtain them.

Second. Simplicity of preparation.

Third. Flexibility of formulæ.

Fourth. Moderate cost of the food.

Fifth. Its preservation.

The uniform purity of materials is the first essential requisite to success. By enlisting the interest and co-operation of honest dairymen, we will find little difficulty in getting milk, even in winter, which will have from twelve to fourteen per cent. of solids and a specific gravity of 1.032. Milk, whether from winter-fed or pastured cattle, should not vary more than one or two points on the lactometer.

The milk for our purpose should not be the same as that intended for butter making; for it is possible to feed cows, according to Brush, so that the fat is increased from the normal standard of four to seven per cent. Therefore, it does not follow that the richer the milk in cream the greater its value for infant feeding. It is of equal importance that the cream with which we supplement our mixtures should be constant. It has been the custom to depend on the supply from various commercial sources. Would it not be better if this added cream were taken from the same milk as that which we employ? This leads us to consider how best we may obtain it. Cream is used for the purpose of restoring the fat which is lost by diluting the cow's milk. Since it is true that woman's and cow's milk contain nearly equal proportions of fat, it is then obvious that our finished mixture should contain exactly as much cream as an equal bulk of undiluted milk. The most convenient and accurate means of replacing this important principle is to set aside enough milk the previous day to correspond to the total amount of water used, and collecting the cream add it to our mixture. For example, if our finished food measures thirty ounces, and is one-third milk and two-thirds sugar water and lime water, then we should add to it the cream from twenty ounces of milk. Another important advantage in this method is that we may raise or lower the cream at will, without materially affecting the bulk of the finished preparation.

The manufacture of milk sugar is now an industry of considerable importance, and its source renders it possible to insure equal purity with that of cane sugar.

Pure water is also an essential feature in the object to be attained; as a rule, it will be found possible to obtain spring water, which, being free from organic impurities, is to be preferred. It has also the advantage of holding a uniform percentage of mineral constituents, which is not true of boiled and variously concentrated river water.

The second requirement is that the prep-

aration of the food shall be rendered simple and easy. Under this heading would occur many minor details, the more important of which may be mentioned. The physician should always determine the proportion of ingredients for each case and write out a formula to serve as a guide to the attendant. The preparation at once of the amount to be used in twenty-four hours is preferable to the making of each feeding separately. The total number of ingredients in any possible modification of the mixture are five; and it is a significant fact that they correspond exactly in number to the elementary principles of the most highly organized foods. They are milk, cream, milk sugar, water, and lime water. The first two should always be mixed together thoroughly, the second two should be made in solution by heat and then added to the former, the lime water being kept aside and added to each separate portion just before feeding, in the proportion of one-fifth of its bulk. The reason for this last precaution is apparent when we remember that heating the lime water deposits a portion of the lime. Lime water is a saturated solution of lime and most saturated when made cold, holding only ten grains of lime to the pint. The sugar required for any formula can most easily be measured with an ordinary boxwood seidlitz powder measure, which may be purchased for a few cents of any druggist. The amount of sugar required in order to bring it up in a mixture to seven per cent. may be easily determined by a simple rule-of-three calculation, remembering that cow's milk contains about four per cent. of sugar, and that a pint of water contains seven thousand grains. The result in grains, divided by the capacity in grains of the seidlitz measure, will give the number of measurefuls required by the formula.

Experience has taught us that no inflexible rule can be followed in adjusting the proportion of ingredients. If an analysis of the mother's milk could always be made prior to the preparation of a substitute mixture, we would find that nature provides a food, variable in its composition yet exactly suited to the special requirements of the individual. This is well proven by the analyses of human milk already made, all of which seem to differ in some particular.

It becomes necessary, then, to adapt the substitute to a great variety of food capacities, and to as many degrees of digestive power. The sound judgment of the physician will be the safest guide as to the relative proportion of ingredients required by individual cases. We have found the plan so long in vogue, of using one-third, then one-half, and lastly two-thirds milk, a good general rule in determining the amount of casein for a given mixture. This allows of changes at the will and discretion of the attendant; for when the milk is reduced the water is increased; and when the total quantity is increased the proportion of milk and diluents may still be preserved.

As a rule, it will be found that the food may contain milk in the proportion of one-third during the first three months, one-half during the next six months and two-thirds during the last three months of the first year.

My own experience has led me to adopt the following general plan as a guide in fixing the amount of food which may be taken:

1st week, 10 feedings of 1 to 1½ ounces each.

2d and 3d week, 9 feedings of 1½ to 2 ounces each.

4th week, 8 feedings of 2 to 2½ ounces each.

2d and 3d month, 7 feedings of 2½ to 3½ ounces each.

4th and 5th month, 6 feedings of 4½ to 5½ ounces each.

6th and 7th month, 6 feedings of 5½ to 6½ ounces each.

8th and 9th month, 5 feedings of 7 to 8 ounces each.

9th to 12th month, 5 feedings of 8 to 10 ounces each.

The question of cost is one of importance to the larger part of those who are concerned. In popularizing our improved methods, they must be shown to be at least no more expensive than others; and it is a fortunate provision in this, as in other matters concerning our welfare, which makes the best the cheapest. Careful calculation will reveal the fact that the average cost of these milk mixtures is about twelve cents per day.

Sterilization is the capstone of this important column. To this do we owe our ability to preserve the infant's food against the numerous destructive agents which abound on every hand. Thoughtful men have for years baked the nursing bottles which were plugged with cotton; others filling them with boiled food have corked and inverted them. Boiling is a simple means of rendering milk sterile; but the temperature required, which is considerably

above the boiling point of water, seems to disintegrate the fats. The atmosphere of live steam, which has a temperature of 212° F. is preferable if it can be made to permeate the flasks and the mixture contained therein. Milk subjected for a long time to this temperature, does not acquire the odor or taste of boiled milk; nor does there seem to be any change in fats or casein.

Several appliances have been devised for the sterilizer. A simple steamer, which may be constructed by any tinsmith, will answer the purpose. A suitable size is one having a depth of thirteen inches and a diameter of nine inches, with an inward flange four inches from the bottom, upon which rests a movable and perforated false bottom. The cover should be loosely fitted, and have a small vent tube running through the handle. For containers in which the separate feedings are sterilized and kept until wanted, I have used chemical flasks (No. 2000) made by Whitehall, Tatum & Co. They are of thin annealed glass, and the steam heat readily permeates them; they are easily cleaned, and in this respect are better that the Erlenmyer flasks recommended by others. The neck being longer the cotton plug is also more easily retained. In order to complete the sterilizing process, it is necessary that the milk should be prepared in bulk and divided in equal portions, so that no two feedings shall be exposed to the air at the same time. These are measured into the flasks, which are afterwards tightly closed with absorbent cotton. They are now placed on the steamer on the perforated false bottom, the water in the lower chamber being kept in a state of ebullition for forty-five minutes. This will be sufficient to destroy all pathogenic bacteria, protect the milk from the causes of fermentation, and insure its preservation for a larger time than is required.

To recapitulate, we have before us a subject, which, though viewed from various standpoints, has recently been given a scientific aspect. Through the slow process of experience, together with the precepts of careful observers, we have been able finally to establish a rational basis for our methods. That cow's milk when modified to correspond to woman's milk is the best substitute, we think is proved beyond question; and also that milk mixtures so constructed as to fulfill the requirements of purity, simplicity, flexibility and moderate cost give us when properly preserved the nearest approach to the food which nature has provided for the infant.

63 New Street.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Forty-first Annual Meeting, at Nashville, Tenn., May 20–23, 1890.

Second Day, Wednesday, May 21.

In the Section on Practice of Medicine Dr. George Fackler, of Cincinnati, read a paper on

Calomel as a Diuretic.

He related the history of three cases of heart disease attended by œdema in which calomel, in doses of about four grains three times daily, usually continued four days or longer, caused decided polyuria and disappearance of ascites and œdema. In most of these cases digitalis and other of the older diuretics had failed. In a fourth case, in which the cardiac trouble was far advanced, calomel also failed to act as a diuretic. The drug, when administered in this manner, caused slight, sometimes severe, salivation and stomatis. He thinks that calomel, and, in all probability, other mercurial compounds, possess diuretic action. If given in proper doses the effect of calomel becomes evident from the second to the tenth day. Continuation of the treatment during diuresis will not alter or increase the effect. Its action is most marked in dropsies due to heart disease; in dropsies of hepatic origin it is not to be relied upon. Pathological changes in the kidney interfere with its action. Small doses are of no use. The diuretic action, in all probability, is due to the irritating effect which mercury exercises during elimination upon the renal epithelium.

Continued Fevers of the South.

An interesting discussion on the fevers of the South was opened by Dr. W. W. Johnson, of Washington, in a paper read by the secretary.

He thinks that enteric fever is a rare disease in the South in the typical or intense

form. There is probably a change going on in the form of enteric fever in the South which has lessened its typical character, so that it is becoming milder. Many cases of mild continued fever which had no well-defined course or symptoms are cases of mild enteric fever, erroneously diagnosticated at times as malarial and intermittent fever. Dr. Johnson thinks there is no good reason to believe there is such a disease as typho-malarial fever.

Dr. George Dock, of Galveston, said that a combination of typhoid and malarial fever has been demonstrated. In Texas, however, they never speak of typho-malarial fever, but they have a continued fever which is commonly spoken of as catarrhal, and the question has been discussed among them whether they have to deal with typhoid fever or a catarrhal fever. As to the latter, there have been no autopsies to show its pathology out of the many cases in which it was said to have been the cause of death. His own opinion is that such cases are usually enteric, though not running a typical course. In half a dozen cases he had verified this view by an autopsy, at which the essential lesions of typhoid were found in the intestines. Those who hold to the separate nature of catarrhal fever adopt a different treatment, giving heroic doses of antipyrine, such as one hundred and fifteen grains three times a day. (!)

Dr. Sears said he had been practicing thirty-five years in Texas, and had there seldom seen typical typhoid fever. But he had treated a large number of cases of continued fever which he had no hesitation in pronouncing purely malarial. They had the mixed types of remittent, intermittent and continued malarial fevers. These fevers, if continued sufficiently long, might take on the typhoid state, as might pneumonia and other affections, especially when badly managed, but it was not really typhoid. The patient should take quinine, and although he did not claim that this drug cured, it did prevent fatal consequences. The recovery might be abrupt or gradual.

A variety of opinions were expressed and the subject was by no means finally settled.

In the Obstetric Section, Dr. W. W. Potter, of Buffalo, presented his

President's Address.

He gave some new ideas as to how the Section should be conducted. He advised that the secretary be elected for a longer time than one year, as in that time a secretary learns only how to be of service and become acquainted with the members. He would have an assistant secretary elected each year, probably from the place of meeting. He urged a prompt and full report of the proceedings of the Section in pamphlet form. He advised the securing of a stenographer. He also thought there should be a vice-chairman elected to fill the place of the chairman in case of unavoidable absence.

He then advocated strict antisepsis in labor, and discussed the traction forceps. He thinks these serviceable in some cases and not to be so sweepingly condemned as on their first appearance. Their assistance often enables one to save both mother and child, as where impaction of the head is accompanied by uterine inertia.

Dr. Franklin H. Martin, of Chicago, read a paper on

Early Vaginal Hysterectomy for Cancer of the Uterus.

He had collected one hundred and thirty-four cases which had been performed since January 1, 1885, with the idea of getting at the future immediate mortality of this operation. The mortality was less than fifteen per cent. Of 25 operations, 4 had been operated on but once; 3, twice; 2, three times; 3, four times; 5, five times; 1, eight times; 1, twelve times; 1, thirteen times, and 1, twenty times. The average mortality of operators having the largest number of cases was but ten per cent. He thinks that vaginal hysterectomy is the most justifiable surgical procedure for cancer of the uterus, and should be attempted at the earliest possible moment after the disease is diagnosticated; because it will remove the entire disease in cancer of any portion of the uterus in a greater proportion of cases than any other surgical procedure now recommended, and will enable the operator to go farther beyond the diseased tissue into healthy tissue than any other surgical procedure. It also leaves the remaining tissues in a less favorable condition for return of the disease than will any other operation. Dr. Martin thinks that vaginal hysterectomy for cancer of the uterus will, in the future, give an immediate mortality among general operators of not more than ten per cent. In the hands of experts this will not exceed five per cent.

Third Day, May 22.

After the meeting was called to order, Dr. Eugene Griscom, Chairman of the Nominating Committee, submitted the following report of the names of the persons nominated by the Committee on Nominations to fill the various offices in the Association for the ensuing year: *President*, W. T. Briggs, M. D., Tennessee; *First Vice-President*, C. A. Lindley, M. D., Connecticut; *Second Vice-President*, R. C. Moore, M. D., Nebraska; *Third Vice-President*, H. C. Wyman, M. D., Michigan; *Fourth Vice-President*, L. P. Gibson, M. D., Arkansas; *Treasurer*, R. J. Dunglison, M. D., Pennsylvania; *Permanent Secretary*, W. B. Atkinson, M. D., Pennsylvania; *Librarian*, C. L. Richardson, M. D., District of Columbia; *Trustees of Journal*, J. B. Hamilton, M. D., District of Columbia; J. V. Shoemaker, M. D., Pennsylvania; D. E. Nelson, M. D., Tennessee. *Judicial Council*, X. C. Scott, M. D., Ohio; W. F. Peck, M. D., Iowa; J. A. Lane, M. D., Kansas; J. H. Murphy, M. D., Minnesota; J. J. Happel, M. D., Tennessee; D. J. Roberts, M. D., Tennessee; A. Garcelon, M. D., Maine.

San Francisco, California, was chosen by the committee as the place of next meeting. Date, first Tuesday in May, 1891. E. L. Shurley, M. D., of Michigan, was appointed to give the Address on General Medicine. Joseph M. Mathews, M. D., of Kentucky, Address on General Surgery. W. L. Schenck, M. D., of Kansas, Address on State Medicine.

The Convention adopted the report of the committee, substituting, however, Washington, District of Columbia, for San Francisco, California, as the place of meeting in 1891. Dr. W. C. Patterson, M. D., was appointed chairman, and C. H. A. Kleinschmidt, M. D., secretary of the local committee.

Dr. Samuel Logan, of New Orleans, then read the

Address on General Surgery,

in which a very careful synopsis of recent progress in surgery was given. The speaker summarized the conclusions of the famous Hyderabad Chloroform Commission, and contrasted with their results the findings of Dr. H. C. Wood and Dr. H. A. Hare, both of Philadelphia. He particularly cautioned against giving chloroform vapor in concentrated form, and against continuing the administration where there is the slightest embarrassment in breathing. Gradual introduction of the vapor is the golden rule in using this agent. Local anæsthesia was briefly discussed, then antiseptics, particular attention being given to Lister's double cyanide gauze. The dry method of wound treatment was advocated on the ground that prompt primary union followed in all suitable cases; drainage was advocated only when the surgeon could not be sure that the wound was aseptic. In cerebral surgery the speaker was greatly influenced by von Bergmann's valuable monograph upon this subject. Abdominal surgery was dwelt upon at length.

Address on Dietetics.

Dr. E. A. Wood, Chairman of the Committee on Dietetics, then delivered the address on Dietetics. He pointed out the evil results which follow the unguided administration of food to children. The jaws and teeth of children should receive their proper exercise, in order that they may attain their proper development. Starch foods washed into the stomach without admixture with saliva are not digested. The average child fed on firm food requiring mastication will grow up with strong, square jaws, and will become a vigorous and well-developed adult.

A report followed from the Committee on American Colleges, advising preliminary examinations for admission to medical schools, annual examinations, and a three years' course.

In the Section of Diseases of Children Dr. W. L. Stowell, of New York, read a paper on

High Temperature in Children,

in which the speaker said that the child's temperature is normally higher than that of the adult. The temperature may be very high from apparently trifling causes, usually nervous impressions or reflex disturbance. All the febrile diseases have what might be called their normal range of temperature, and it does not indicate treatment unless excessive or out of its normal course. Antipyretics are to be used with caution, lest while they lessen fever they, by weakening the heart, lessen the chance of favorable termination of the disease. The temperature may often be lessened indirectly by heart tonics, general tonics and food. The tendency of nutrition in childhood is towards growth and repair, not degeneration, hence

careful nursing and feeding will do more towards a favorable result than drugs.

Duality of Croup and Diphtheria.

Dr. Carl Seiler, of Philadelphia, in opening the discussion on the duality of croup and diphtheria, said that in his belief they were certainly different diseases. In diphtheria there is always a peculiar characteristic odor about the body and a marked difference between the membrane found in the two states. Again, diphtheria comes suddenly, while croup develops slowly. The poison of diphtheria varies very much in its effects in children of the same family sick at the same time.

The discussion was continued by Dr. Porter, of St. Louis, and Dr. Jackson, of Syracuse. Dr. E. R. Early then read a paper on "Croup," in which he gave the history, clinical features and treatment of the disease.

In the Section of Practice of Medicine, Materia Medica, and Physiology, a number of papers were read by title, after which Dr. J. M. French, of Cincinnati, Ohio, read a paper on "Oxygen; its True Value as a Therapeutic Agent." Dr. E. L. Shurley, of Detroit, Mich., then read a paper on "The Local Treatment of Phthisis Pulmonalis," in which he advocated the local use of creasote by a modification of insufflation and forced inspiration. Dr. W. B. Davis, of Cincinnati, read a paper entitled, "Functional Albuminuria."

Periscope.

A Case of Tetanus. Recovery.

The following case of tetanus, followed by recovery, is reported by Dr. George H. Stroup, in the *University Medical Magazine*, Feb. 1, 1890: John R., 31 years old, colored, coachman, while walking over some old lumber accidentally fell on a projecting nail which entered the knee at outer side of right patella, to the depth of an inch. He pulled it out immediately, and thought little of the occurrence until five days after, November 2, 1889, when he experienced peculiar pains and hardness of the muscles of his back, also stiffness of the neck, a contraction of the facial muscles and a staggering gait.

About 8 o'clock the same evening Dr. Stroup was summoned very hastily to see the man, and found him in all the agonies of tetanus: jaws locked, muscles stiff, back arched, the whole body rigid, and with great drops of perspiration on his face and neck. Dr. Stroup immediately ordered a tub, hot water, blankets, and a clothes-horse, over which the blankets were placed. With considerable difficulty he was stood in the tub while the hot water was poured over him. After one hour and thirty minutes of this steaming treatment he regained some control over his muscles, and asked to be let out. The muscles appeared to be relaxing, and he was able to bend the knee down into the tub. Fifteen minutes later 30 grains of bromide, with 10 drops of chloroform were forced into his mouth; in 20 minutes he cried to be let out. Thirty grains more of bromide with 15 drops of ether were given. The steam and heat under the blankets were by this time intense, and, as the patient seemed to be about fainting, he was taken out and given 30 grains more of bromide with 20 grains of chloral. He was then wrapped in blankets and put to bed.

Dr. Stroup did not leave him until midnight. At one o'clock he was again summoned. The muscles were twitching, and stiffness of the jaws again commencing. Sixty grains of bromide with 20 grains of chloral were immediately given; in half an hour he was alseep, and did not awake until 5 o'clock Sunday morning. On waking he could open his mouth sufficiently to say he had pain at the knee and stiffness in his jaw. Some milk and beef tea was given. As he had intense craving for water, he was given some in a glass; he had no sooner swallowed it than the convulsive movements commenced again; this occurred every time water was taken. Chicken broth was then prepared, but it acted in the same way as the water. Milk and beef juice were all he could take without producing convulsions. A small piece of meat was put into his mouth but he could not close the jaws to chew it.

About 3 P. M., November 3, Dr. Stroup was again summoned. The messenger said he was dying, and on arriving at his room he was found to be suffering from all the acute symptoms first described, and was evidently dying. A hypodermic injection of morphia and cocaine was given at once, one-half grain of each. As this appeared to do very little good, in half an hour two more doses of one-quarter grain each were ad-

ministered in succession. In about twenty minutes, seeing very little effect from the injections, and thinking he must surely die, Dr. Stroup plunged a tenotomy knife into the cicatrix where the nail had entered, cutting down deeply. He had no sooner withdrawn the blade than the muscles, which were so rigid that five men who were assisting could not bend the arm or leg, almost immediately relaxed, and the patient cried: "Oh, Doctor, don't!" The wound made by the knife was filled with iodoform and the leg bandaged.

From this time to the end of the first week there was considerable stiffness of the jaw with pain at the knee, the pain gradually passing down the leg to the great toe, after which it disappeared entirely.

During this first week the patient took daily 120 grains of bromide with the same amount of chloral; at the end of the second week he was out of bed, and by the end of the third week was walking about. His subsequent recovery was complete.

Powdered Meat.

As long ago as 1874, Dannecy, Chief Pharmacist of the hospitals of Bordeaux, prepared an excellent article of food for invalids by making a powder of meat. He took meat, chopped it very fine, and spread it upon muslin, drying it by means of a current of air. In this way he obtained a friable mass, which was easily powdered. It was administered by adding it to beef tea or spreading it upon bread. It could also be mixed with the ingredients used for making biscuits, and this combination was found to be especially suitable for administration to children.

In the same year Yvon suggested the following method of preparing a palatable meat food: Take of raw meat (filet of beef), 250 parts; of charred sweet almonds, 75 parts; of bitter almonds, 50 parts; of white sugar, 80 parts. Rub slowly in a mortar until a homogeneous paste is obtained, adding from time to time a sufficient quantity of water to give a proper consistency for a semi-solid or a liquid mixture. In the liquid preparation the meat will settle after awhile, but may be dispersed through it by shaking. The preparation may be preserved for a long time if bottled and kept in a cool place; and its nutritious character may be enhanced by adding to it the yolks of one or more eggs.

Cremation in California.

Dr. Walter Lindley, of Los Angeles, in his opening address before the Medical Society of the State of California, says that there appears to be a general revival of cremation as a method for the disposal of the dead. The Cremation Society of Southern California was incorporated about three years ago. Its building consists of a neat chapel, connected with the furnace-room by a large sliding door. The main object of the Society has been to furnish a quick and powerful heat, without allowing the flames to come in contact with the body. No direct currents of air pass over it; the heat is still and of a temperature of about 2,000° F., doing its work in less than an hour, and permitting none of the essential particles to escape. No other crematory exists west of the city of St. Louis. The Society has had about thirty cremations, all of which are said to have been highly satisfactory in their methods and results. While Dr. Lindley does not see any imperative reason at present for adopting this method, yet, as our land becomes more densely populated, it will become incumbent upon us, as a profession, to lead the way — for sanitary reasons — to some method of disposing of the dead, different from the present method of sepulture.—*Occidental Med. Times*, May, 1890.

A Long Fall.

A remarkable fall of a miner down 100 metres of shaft (about 333 feet) without being killed, is recorded by M. Reumeaux in the *Bulletin de l' Industrie Minérale*. While working with his brother in a gallery which issued on the shaft, the man forgot the direction in which he was pushing the truck: so it went over, and he after it, falling into some mud with about three inches of water. As stated in *Nature*, he seems neither to have struck any of the wood *débris*, nor the sides of the shaft, and he showed no contusions when he was helped out by his brother after about ten minutes. He could not, however, recall any of his impressions during the fall. The velocity on reaching the bottom would be about 140 feet, and time of fall 4.12 seconds; but it is thought it must have taken longer. It appears strange that he should have escaped simple suffocation and loss of consciousness during a time sufficient for the water to have drowned him.—*Science*, April 11, 1890.

The "Lancashire Cure" for Hydrophobia.

A curious instance of the readiness of the lay mind to accept statements on the efficacy of methods of treatment without the necessary support of scientific evidence has just been shown in the resolution of the Rabies Order Committee of the Heywood Town Council to recommend the council to grant a testimonial under the corporation seal to the owner of a secret "cure for hydrophobia." It appears that last November five persons in Heywood were badly bitten by an alleged mad dog, and were treated by this "cure" on the recommendation of the chief constable of Clitheroe. The statement was made that the remedy had been in existence for over 100 years, a writer in the *Gentleman's Magazine* in 1783 saying that 400 cases had been successfully treated by it. Since then it was said "that 600 more cases had been treated, and not a single failure." As everything, of course, turns upon the actual rabidity of the animals inflicting the bites, nothing can be inferred from such statements; but as to the Heywood cases, it may be pointed out that, if actually rabid, it is still somewhat premature to present testimonials in support of the efficacy of the remedy.—*Lancet*, May 3, 1890.

Druggists' Charges.

Complaints having been preferred to the Austrian authorities to the effect that the apothecaries at certain fashionable springs and health resorts were demanding very high prices for filling prescriptions, and otherwise overcharging, an investigation was recently ordered the result of which was an official "warning" to all apothecaries at "*Bade und Kurorte*" notifying them that they must closely adhere to the scale of prices in force in Vienna. This led to replies, which set the authorities to investigating the tariff of the Viennese apothecaries, and the result was a discovery that some of these had been heavily overcharging. Thus the matter stands at last advices.—*National Druggist*, March 15, 1890.

International Sanitary Regulations.

One of the most important questions which has been submitted to the Pan-American Congress was, undoubtedly, that which asked for a decision upon means tending to prevent the conflict which may arise at the time of epidemic invasion between the diverse sanitary regulations which the American nations have seen fit to adopt in order to shield themselves from such invasions. A committee was appointed to examine the work of special sanitary congresses and conferences, which have met at different times in several parts of the world; and it has reached its conclusions by accepting the results of exhaustive studies, made by men eminent in the profession in Europe as well as in America. The report of the committee, which was adopted by the Congress, says that complete isolation, which, theoretically, appears to be the most effective prophylactic against the invasions of epidemic diseases, does not afford, in practice, satisfactory results as a sanitary measure, but tends, on the other hand, to notably injure the commercial interests of the countries. Dr. Francisco Rosas, President of the Sanitary Congress of Lima, thus expresses himself on this point: "It is scientifically demonstrated by innumerable facts that the closing of ports and frontiers does not prevent the invasion of epidemics; that these enter and develop with greater violence in the countries which pretend to isolate themselves, because, under the mistaken belief that they are free of all danger, they disregard the proper means to restrain the development of the epidemic, and, above all, to lessen its severity."

But, if absolute isolation, as a prophylactic, is nothing more than an illusion, the same may not be said of the sanitary means that modern science has placed within our reach for the disinfection of infected localities, as well as to prevent the introduction and development of contagion in those which have remained in a state of health.

The committee, in conclusion, suggests that, although it does not appear that the plans of the Sanitary Congress of Lima, of 1889, have passed into the category of international compacts, it is to be hoped that they will be accepted by the governments that participated in the said Congress, because those plans were discussed and approved by medical men of acknowledged ability.

If these were duly observed in all America they would prevent, under any circumstances, the conflict which usually arises between the obligation to care for the public health and the principle of freedom of communication between countries.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

OBJECTIONABLE CENSUS QUESTIONS.

A natural feeling of surprise has been excited by the printed questions which have recently been sent to physicians in the United States, asking them to report to the Census Office the names of persons suffering with a variety of chronic diseases and defects. To the immediate and general expressions of disapproval which came from physicians in different parts of the country, a certain concession seems to have been made by the issuing of instructions to the enumerators that, when replies to questions of this sort are refused, they are to mark "refused to answer" opposite the questions, in their returns, and not to attempt to impose the penalty which the law provides for refusal. It is stated in this connection that "all legal proceedings will be instituted by the Washington office."

It is to be hoped that this means that no such proceedings will be instituted; for we cannot see how the Census Bureau could insist upon pushing to a conclusion the foolish provisions of the law under which they are operating. As a rule the inhabitants of any country should submit to the impositions of law-makers whom they themselves have chosen, and they should also be willing to admit that there may be good reasons for what seems to them entirely unreasonable, and therefore submit without cavil. But there are occasions when it is proper to refuse obedience to laws which appear to a large and intelligent and conscientious body of citizens to be unjust or unwise, especially if such refusal has a reasonable chance of leading to the repeal or suspension of such laws.

The present occasion we believe to be such a one, and we think it right and not unwise to suggest to the readers of the MEDICAL AND SURGICAL REPORTER that they refuse to furnish the enumerators or the Washington Office with the names of persons of whose defects or diseases they have become informed in their professional and confidential relations with them. We have no doubt that the attempt to make witnesses of physicians, except in courts of justice or tribunals to which the functions of courts are attached, is unconstitutional, and cannot be carried out.

We have no idea that the Census Office will proceed against any one who declines to disclose the professional confidences of his medical experience; and, if it should, we have no idea that the courts will sustain it in doing so.

The Editor of the REPORTER will decline to answer the questions referred to, on the grounds indicated above, and he hopes that all the physicians in the country will do the same; because the more there are who do this, the stronger will be the force of the protest against what we all must think to be a false step on the part of the framers of these inquisitorial questions, and a serious

invasion of the rights of those who have committed to us secrets of the most sacred character.

TREATMENT OF AGGRAVATED CASES OF HEMORRHOIDS.

Piles are well known to be a very common disease. In very many cases they do not require operative treatment, as their causes —such as produce a determination of blood to the rectum or retard its return—can be obviated by general medical and local treatment. The numbers of operations which have been performed for piles, and the fact that there are not a few men who devote themselves to diseases of the rectum as a specialty, indicates that there is a large number of cases left in which operative treatment is necessary. In a few of these the disease is so aggravated by continuance for years as to justify heroic measures. It is for such cases that Dr. Lewis S. Pilcher, in the *Annals of Surgery*, May, 1890, recommends what is known as Whitehead's operation. In these cases, he says, the surgeon has no longer to do with a simple varicose condition of the hemorrhoidal veins, nor with a fairly well defined and circumscribed polypoid hypertrophy of the vessels and submucous tissues, but with a true angeioma, which, although on its surface it may be more or less tabulated, in its deeper portion is formed by a continuous network of dilated vessels or cavernous spaces bound together by a varying amount of connective tissue. These tumors are richly supplied with blood from terminal branches of the middle meningeal artery, which descend to them almost vertically in the submucous coat of the rectum. A dozen of these vessels may require tying in the worst cases. Their pulsation can be felt by introducing the finger into the rectum above the tumor Dr. Pilcher has had six cases of the kind described ; the patients were all in the prime of life, between thirty and forty years of age, and in all but one the piles dated back to their early youth. This fact is held to indicate an original inherent developmental defect in the vascular network at the lower end of the rectum. Associated with the angeioma are œdema and relaxation of the adjacent mucous membrane and of the sphincter, which add greatly to the sense of weight and discomfort. But, notwithstanding the apparent gravity of the disease and the great drain upon the patient's strength by loss of blood and mental and physical suffering, the tumor occupies usually only from an inch to an inch and a half of the rectum, and is superficial, involving only the mucous membrane and the submucous connective tissue, so that it may be enucleated readily from the sphincters. These considerations make the operation of excision, or Whitehead's operation, the most certain method of disposing of the tumor.

Regarding the danger of the operation, nothing more need be said than to quote the results of Mr. Whitehead, which he reported to the British Medical Association, in August, 1886. He had up to that time operated on more than three hundred patients, without a death, a single instance of secondary hemorrhage, or a single case in which any complication, such as ulceration, abscess, stricture or incontinence of feces had occurred. Mr. Whitehead further stated that, to the best of his knowledge, every patient had been completely and permanently cured. Nevertheless Dr. Pilcher thinks it should be ranked as a major operation, and that in the hands of an unskilled operator it would justify the opinion of Kelsey, that it is "naturally difficult, tedious and bloody."

The cautions which Dr. Pilcher advises are important. In the first place care should be taken not to injure the sphincter, lest incontinence of feces result. It is by no means easy to recognize the fibres of the sphincter, especially when the tumor is large and the muscle flabby, and the additional preliminary stretching has entirely relaxed it. The first steps in the operation, therefore, should be characterized by great care

in the identification and avoidance of the sphincter. When, he says, the muscle has been identified and drawn aside at a given point, the further enucleation may be done with expedition and without danger to it.

A second caution pertains to the tumor itself. If care is not taken to keep close to the surface of the muscle, and thus to keep outside of the vascular tissue of the tumor proper, the process of enucleation will be more difficult and will be attended with an unnecessary amount of venous hemorrhage. When, however, the sound tissues beyond the tumor have once been reached at any point, the further enucleation may be accomplished readily and safely by pursuing the enucleation circularly around the bowel from this point, and working downward to the anus. The dissection should be pushed well upward beyond the diseased portion and at all points, at the same level, so that the final transverse section shall pass through healthy tissue, and so that there shall be no redundancy of tissue at any part from which ectropion ani might result. None of the skin, however, should be cut away; for, while at the time of suturing the sutures will be well outside the anus, as time passes the walls of the rectum will regain tonicity and retract upward until finally the line of sutures disappears within the margins of the anus.

This operation, it will be remembered, Dr. Pilcher recommends now only in the most aggravated cases of hemorrhoids. His judgment is that it is based upon sound surgical principles and that it is a valuable and permanent addition to operative surgery. There can be no question that the operation is thorough and complete, and with the testimony of two such trustworthy surgeons as Mr. Whitehead and Dr. Pilcher there would appear to be no doubt that it is relatively free from danger in skilled hands; it is therefore probable that with those who have experienced its merits it will become more popular.

TREATMENT OF STRICTURE BY THE RETAINED SOUND.

The difficulty of treating certain cases of stricture of the urethra, especially when all the appliances of urethral surgery are not at hand, is often very great; and medical practitioners may regard with more than ordinary interest any method which promises to lessen this difficulty. Such a method has been proposed by Gueterbock, in an article in the *Deutsche Zeitschrift für Chirurgie*. It consists in the introduction into the urethra of a fine flexible bougie, or sound, and leaving it in place for three days. The sound should not quite fill the caliber of the stricture, and will thoroughly drain the bladder, as is well known to be the case with solid instruments left in the urethra. Gueterbock states that after the sound has remained in place for three days, on its withdrawal it will be found that the urethra will admit an instrument corresponding to its normal caliber.

In using this method it is important that the urethra shall be thoroughly cleansed of all pus or other material capable of exerting a deleterious influence upon the mucous membrane, and that the bougie shall be rendered aseptic.

The explanation of the action of this method is that the bougie, by its presence, promotes relaxation and softening of the tissue of the stricture. Gueterbock says it is especially indicated in cases in which great irritability and sensitiveness is produced by the introduction of dilating instruments, and when these symptoms cannot be relieved by narcotics, or are accompanied with a tendency to hemorrhage; in cases of injuries produced by the catheter, especially in cases of false passages; in cases in which the stricture is difficult to enter, in consequence of its eccentric position or the valvular character of its orifice, and in cases of necessity, where it is desired to give the urethra a normal caliber as expeditiously as possible, without resorting to cutting or divulsion.

The treatment of stricture of the urethra with retained sounds is contra-indicated in cases of stricture calling for more forcible methods; further, in strictures with exceedingly callous tissue; and, finally, when the urine is very irritating and likely to injure the mucous membrane if kept in contract with it for any length of time.

The statement of these indications and contra-indications will probably suggest that the method is hardly to be regarded as a panacea, and also that it is hardly to be expected that it would always bring a strictured urethra in three days to such dimensions that it would admit an instrument corresponding to its normal caliber. Nevertheless, it would probably be worth while to give the method a fair trial; for if it accomplished much less than is claimed, it might still be a great boon to medical men and their patients.

MASTURBATION.

A physician, brought more or less constantly in contact with cases suffering or supposed to be afflicted with disturbances connected with the misuse of the generative organs, witnesses, in the majority of instances, humanity in the picture of abject misery. Most persons so afflicted, before consulting a regular practitioner of medicine, have read and re-read advertisements in the secular press of the untold evils resulting from their supposed condition, with the natural consequence of working up their mental imaginations to a state that beggars description, and makes them an easy prey to the so-called specialists. It is not to be wondered at, then, that many, particularly those who practice masturbation, some of whom are naturally weak-minded, wind up their career in insane asylums. Such being the case, it behooves the medical profession to adopt some measures to counteract, if possible, this tendency of consulting quacks, with its attending evils. The so-called popular lectures upon these subjects do but little if any good in this direction; in fact, their tendency, according to good authority, is harmful rather than otherwise. The family physician, in a quiet way, with a little tact, can exert a wonderful influence in ameliorating these evils, which to-day are sapping the vitality of many of America's youth.

In masturbation we have a habit, the practice of which is found to occur under a variety of circumstances. First, in very young children, arising from some local irritation, want of cleanliness, etc.; secondly, in individuals who have passed, reached, or are near the age of puberty, and have either accidentally learned or been taught this pernicious habit; thirdly, a class of cases may be mentioned in which the practice has a central origin, in certain forms of brain-disease or cerebral deficiency, as is seen in some forms of insanity and in idiocy.

Excluding the last class of cases, we have two classes, in which the physician may deal hygienically and morally as well as remedially. If every physician made it a habit to carefully examine the new-born infant in respect to its genitalia, separating any adhesions to the glans penis, and would then instruct the parent as to the proper method of keeping the parts clean, one cause of irritation to the male organ would be removed.

In the second class of cases the moral aspect of a physician's duty is exemplified. As the family medical adviser, he should see to it that the youth approaching manhood is notified by either the parent or himself of the serious constitutional effects the indulgence in masturbation will produce. Such information, coming from such sources, cannot fail to accomplish some good, sooner or later.

Leaving those cases of self-abuse requiring only moral persuasion and advice, we will devote a few moments to the consideration of persons who have masturbated excessively and who are suffering from the nervous shock incident to the oft-repeated orgasm. It is in such cases as these that the quack finds the largest and most lucrative field for

his nostrums. It is in just such cases that his pamphlets and circulars, under alluring titles, find eager perusers, and do a harm that can scarcely ever be corrected.

In the treatment of these cases, much can be done by advising brisk exercise, of both mind and body. Early rising and careful diet should be recommended. Remedies directed towards the treatment of symptoms connected with the nervous, circulatory and digestive systems will be required. Lastly, but by no means least, the physician must gain the patient's entire confidence, not by wounding and severely censuring, but by sympathy and encouragement; trying to elevate him out of his bad habits, in such manner as discretion and the patient's disposition may suggest. Such a course will succeed in the largest number of cases, provided time and sufficient attention be given.

READING AND THE PENNSYLVANIA STATE MEDICAL SOCIETY.

At its last meeting the Berks County Medical Society adopted a resolution instructing the delegates who will attend the meeting of the State Medical Society at Pittsburgh, June 10, to extend an invitation to that body to meet in Reading in 1891. To defray the expenses for the entertainment of delegates the members of the Society obligated themselves to raise the sum of $1,000, and it is the purpose of the Financial Committee to call upon citizens in general to lend their aid in meeting the expenses incident to the occasion.

The State Society has not met in Reading since 1848, and the members of the profession there would be very much gratified if it would come to them in 1891. They are prepared to give the Society a hearty welcome, and the more so since they are now working with great activity and harmony in the interest of medical science. As the meeting of the Society this year is to be in the extreme western part of the State, it might naturally meet in the eastern part next year.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

SPINAL CONCUSSION: Surgically considered as a cause of spinal injury, and neurologically restricted to a certain symptom group, for which is suggested the designation Erichsen's Disease, as one form of the traumatic neuroses. By S. V. CLEVENGER, M. D., Consulting Physician Reese and Alexian Hospitals, Chicago. With thirty wood-engravings. 8vo, pp. v, 359. Philadelphia and London: F. A. Davis, 1889. Price, $2.50.

Much attention in recent years has been given to a study of injuries to the spine occurring in railway collisions. Many suits for damages on account of such injuries have stimulated specialists in nervous disease to a critical study of their pathology. In the present work, Dr. Clevenger has endeavored to review carefully the entire subject. His general conclusion is, that the spinal sympathetic system is the main seat of the disease, and that in consequence the cord functions are deranged. The author discusses the writings of Erichsen, Page and Oppenheim, and gives illustrative cases from his personal observation and from the published cases of others. He prefers to call the results of spinal concussion Erichsen's Disease. Of this he gives the symptoms, diagnosis and the differential diagnosis from various forms of myelitis and meningitis, hysteria, and from other conditions liable to cause spinal symptoms.

The treatment of spinal concussion is dismissed with very brief consideration. He thinks it safe to treat the initial stages as those of a severe strain, with hot fomentations, rest in bed, or sitting, as the patient feels the most comfortable. Darkness and quiet are necessary, and disagreeable mental influences should be removed as much as possible. Excitement of all kinds and stimulants must be avoided. Ergot, he says, gives far better results than the bromides. It should be given in doses of from ten minims to a fluid drachm, three or four times daily, to allay the pain in the back and irregular circulation.

The final chapter, on medico-legal considerations, contains a bitter denunciation of the system of medical education in this country, and of the cupidity and rascality of many practitioners. In declaring, however, that "it is the physician's duty to coach the attorney, in and out of court, whether he testify or not," he declares in favor of a practice which makes physicians partisans in a suit instead of disinterested advisers of the court—their highest medico-legal function.

The publication of Dr. Clevenger's book is timely. It is evidently written by a man who has strong personal convictions on the subject, and who is not afraid to maintain them. The book will be consulted with profit by all who are interested in spinal concussion, especially from a medico-legal point of view, and it is a valuable contribution to that subject.

FOOD IN HEALTH AND DISEASE. By I. BURNEY YEO, M. D., F. R. C. P., Professor of Clinical Therapeutics in King's College, London, etc. 8vo, pp. x, 583. Philadelphia: Lea Brothers & Co. Price, $2.00.

Dr. Yeo has divided his book into two parts; in the first he treats of foods in health, and in the second of foods in disease. The nature, origin and purpose of food are mentioned, metabolism described, and the various articles of food taken up particularly and their usefulness indicated. The author goes at some length

into dietaries suitable for soldiers, seamen and prisoners. Food in infancy and childhood receives a fair share of attention, due acknowledgment being made to Dr. Louis Starr for his writings on the subject.

In the second part of the book feeding in acute diseases in convalescence, and in various affections of the stomach, liver and kidneys is considered. The dietetic treatments of obesity of Banting, Ebstein, and Oertel are clearly presented and their differences pointed out. None of the methods, the author justly says, is appropriate to the treatment of all cases of obesity indiscriminately, while any one of them may prove successful in suitable instances. Dr. Yeo also discusses the dietetics of anemia, neurasthenia and phthisis, and under the first two diseases very naturally quotes freely from Weir Mitchell. A selection of hospital dietaries and dietaries for invalids forms a fitting conclusion to the volume.

The appearance of this book is timely, and its subject-matter both interesting and valuable. It would be a revelation to many physicians to learn how much in the way of prevention and treatment of disease can be accomplished by a proper selection of the food. The question of the suitability of various foods to meet certain conditions is one of the greatest importance; Dr. Yeo is to be congratulated on having thrown some light on it, though it must be admitted that a good deal of obscurity still surrounds it.

DIE SYPHILITISCHEN FINGER UND ZEHENENTZÜNDUNGEN, von Dr. Karl Koch, in Nürnberg. SAMMLUNG KLINISCHER VORTRÄGE. No. 359.

SYPHILITIC INFLAMMATIONS OF THE FINGERS AND TOES. By Dr. Karl Koch, Nürnberg. 8vo, pp. 40. Leipzig: Breitkopf and Härtel. April 21, 1890. Price, 75 pfennigs.

Dr. Koch gives a long and detailed description of the inflammations of the fingers and toes occurring in connection with syphilis. The cases are not frequent. The literature is scanty. The author distinguishes several varieties: a cutaneous or subcutaneous, a periosteal, an osseous or medullary, and an articular. One may lead to the other. Still there may be an independent inflammation of a joint. Koch prefers the general designation, doctylitis. Bone is more frequently involved than soft structure. In young children osteomyelitis is the more common, in adults periostitis. Tendons and their sheaths may participate in the process. These inflammations appear as late manifestations of syphilis. Pathologically, the fibrillary connective tissue and the vessels, especially the adventitia, are the seats of the process. Diagnostically, the distinction is to be made from tuberculosis, gout, diabetes and neoplasms, sarcomata and enchondromata. The prognosis is not bad if appropriate treatment is instituted early.

Literary Notes.

—The *Cosmopolitan* has become one of the most attractive of the American monthly magazines. The June number deserves special notice; the illustrations are graceful and artistic, and the class of articles is excellent. S. G. W. Benjamin's "Farm Life and Irrigating in Persia" gives many new ideas of this Oriental people, while Rollo Ogden's article on "Leading Writers of Modern Spain" will prove interesting to all lovers of literature. In this number Miss Bieland takes us with her through Japan; each step of her flying trip being illustrated.

—The House Committee on Patents has ordered a favorable report on a bill which is identical with the International Copyright bill already acted upon adversely by the House, with the addition of a new section, which provides that it shall be of effect only where reciprocal advantages are granted by foreign countries to American authors.

—With the May issue, the *Sammlung Klinischer Vorträge*, which for twenty years has been under the editorial direction of Richard von Volkmann, passes into the hands of Ernst von Bergmann, Wilhelm Erb and Franz Winckel, representing the departments of surgery, medicine, and gynecology and obstetrics. The May number will contain papers from the pen of each: by von Bergmann on Tubercular Ostitis in and at the Atlanto-occipital Joint; by Erb on Dystrophia Muscularis Progressiva; by Winckel on the Rupture of Extra-uterine Gestation sacs.

Correspondence.

The Questions asked by Medical Examining Boards.

To the Editor.

Sir: In the Reporter, April 19, page 464, is an article quoted from the *Northwestern Lancet*, giving answers from applicants to the State Board. These speak for themselves. They show a great necessity for some such examining body. They were, however, probably published by our State Board to gain favor with the profession abroad and the public at large. They were also given to our daily press, and were written up in quite a sensational style. Our State Board is not endorsed by quite a large body of the resident physicians. They have sought to make for themselves a reputation of being strict, and have resulted in being ridiculous and often unjust. I am thoroughly in favor of advanced medical education, but in a practical way. I write, not so much to find fault with our own Board as to bring the matter before the profession, that if possible these things may be avoided elsewhere. The law here makes no appeal from the Board. It is true one can appeal to the Governor, but the examination papers are simply referred to and the percentage counted. There is no appeal from unreasonable questions. The papers are prepared by each individual member of the Board, but they are not present at the examination. Quite often questions are ambiguous, and the applicant has no means of knowing the real meaning. The time allowed for examination is often entirely out of proportion to the work re-

quired. When the writer passed before that body, we were given fourteen or fifteen *topics* to write upon, in obstetrics and gynecology, and had an hour and a half in which to do the work. In practice, the examiner was a specialist and gave but four out of ten questions that the general practitioner would ever meet. In surgery we had two subjects, and the ten questions went into the minor details of two chronic troubles that a man may not see in a lifetime. There was not a single question on acute surgery. The whole examination seemed to be a bid for men fresh from the schools and crammed for an examination.

From what I see of examination papers before and since, they have followed the same plan. Some of the examinations were quite fair and showed an endeavor to get practical answers. Let us have longer study in the medical schools, more restrictions in admissions to them, and let us have also examining boards; but let us have with them all, common sense. A picked list of questions would put our Board in as unfavorable a light as the applicant referred to in the *Northwestern Lancet.*

Yours truly,

C. A. Donaldson, M. D.

Parker, Minn.,
May 20, 1890.

Notes and Comments.

Pennsylvania Medical Society.

The programme of the fortieth annual session of the Medical Society of the State of Pennsylvania, to be held at Pittsburgh, June 10–13, provides for the first day an address of welcome, by Dr. E. A. Wood; an address on medicine, by Dr. J. C. Wilson, Philadelphia; an address on hygiene, by Dr. T. J. Mays, Philadelphia; a report of 340 cases of labor, by Dr. J. M. Batten, Pittsburgh; a report of a case of sarcoma of choroid, by Dr. Wm. C. Bane, Pittsburgh; and a paper on value of measures over medicines, by Dr. J. Madison Taylor, Philadelphia.

In the evening of the first day, President Dr. J. B. Murdock will deliver his Presidential Address.

On the second day there will be an address in laryngology, by Dr. Wm. H. Daly, Pittsburgh; and papers on diet in therapeutics, by Dr. Solomon Solis-Cohen, Philadelphia; trephining in traumatic insanity, by Dr. Samuel Ayers, Pittsburgh; needed legislation in the treatment of dipsomania, by Dr. T. D. Dunn, West Chester; report of the Committee on Clinical Research, by Dr. John B. Roberts, Chairman; report of the Committee on Management of Pennsylvania Hospitals for the Insane, by Dr. Samuel Ayers, Chairman; an address on surgery, by Dr. John B. Roberts, Philadelphia; papers on the intraocular syringe in cataract extraction, by Dr. J. A. Lippincott, Pittsburgh; management of obstinate dropsies, by Dr. James Tyson, Philadelphia; chemistry of cooking, by Dr. Traill Green, Easton; the present status of the code of ethics, by Dr. J. H. Packard, Philadelphia; the value of primary anæsthesia from ether, by Dr. J. H. Packard, Philadelphia; prolapsus of the rectum in children, by Dr. H. R. Wharton, Philadelphia.

On the third day there will be an address in obstetrics, by Dr. Frances N. Baker, Delaware Co.; papers on rational midwifery, by Dr. J. Milton Duff, Pittsburgh; what should be required of an abdominal surgeon, by Dr. M. Price, Philadelphia; suppurating ulcer of cornea, by Dr. Edward Jackson, Philadelphia; the report of Committee to Revise the Constitution of the Medical Society of Pennsylvania, by Dr. Wm. M. Welch, Philadelphia, Chairman; an address in mental disorders, by Dr. Alice Bennett, Norristown; the physiological and therapeutic action of sulphur, by Dr. John V. Shoemaker, Philadelphia; the application of dry heat by steam, by Dr. G. M. Shilito, Allegheny; errors of refraction developed by loss of accommodation, by Dr. G. H. Cline, Jersey Shore; report of Committee on Medical Examiners, by Dr. L. F. Flick, Chairman; a paper on la grippe or epidemic influenza, by Dr. A. B. Braumbaugh, Huntingdon; report of Committee to Confer with State Committee on Lunacy, by Dr. H. C. Wood, Chairman; report of Committee on Pharmacy, by Dr. J. W. Holland, Chairman. Unfinished business.

Medical Society of New Jersey.

The one hundred and twenty-fourth annual meeting of the Medical Society of New Jersey will be held in the Heath House, Schooley's Mountain, June 10 and 11, 1890, commencing at 4 o'clock P. M., June 10. The programme provides for Tuesday an

annual address by the President, B. A. Watson, M. D., Jersey City, "A Historical Sketch of Surgery," and discussions upon subjects presented at last Annual Meeting: (1) Does the Early Administration of the Salicylates in Acute Articular Rheumatism Prevent Heart Complications? The discussion to be opened by Dr. E. J. Marsh. (2) Hydrophobia. The discussion to be opened by Dr. W. P. Watson. (3) Is Diphtheria Primarily a Local or General Disease? The discussion to be opened by Dr. U. Selover.

On Wednesday the Third Vice-President, Dr. Geo. T. Welch, will deliver an address on "Fathers and Sons;" and essays will be read by Dr. E. L. B. Godfrey, on Endometritis, and by Dr. Orren B. Gross, on "A Few Rare Cases of Abdominal Surgery."

Further information may be obtained by addressing Dr. E. P. Cooper, Troy Hills, Chairman of the Committee of Arrangements, or Dr. William Pierson, Secretary of State Medical Society, Orange, N. J.

Conference of State Boards of Health and Quarantine.

The National Conference of State Boards of Health met in Nashville May 19. Delegates were present from nineteen States. Resolutions were adopted urging, in case of an outbreak of yellow fever, such co-operation in administration on the part of the Northern States as will confine the disease to the point of initial attack, in place of the expensive, unscientific and unsatisfactory so-called quarantine at distant State lines. A resolution was also adopted urging upon the health authorities of each State the importance of such administration of any quarantine they may establish as will furnish protection to and show due regard for the rights of States lying beyond them.

Regulating the Practice of Medicine in Washington, D. C.

A bill introduced by Senator Ingalls, by request, to regulate the practice of medicine in the District of Columbia was reported May 24 from the Committee on the Affairs of the District. It provided originally for the appointment of a Board of Examiners to examine applicants for license to practice, which should consist of fifteen members, five of them homœopaths. The Committee amended the bill, so as to give the eclectic school two representatives on the Board, leaving the regulars with a majority of one.

Trinity University a Diploma-Mill.

Dr. P. Ripley Bradbury, who calls himself Dean of Trinity University (of Vermont), was arrested in Wakefield, Massachusetts, May 28, on the charge of using the mails in aid of a scheme to defraud in connection with alleged bogus diplomas. This concern is a diploma-mill and was exposed by the *Boston Herald*, September 29, 1889.

The Census and Benefit Societies.

Any one interested in the sick-benefit, funeral-aid and death-beneficiary associations of the United States can help make the statistics of their organizations for the forthcoming census more complete and disseminate the knowledge of the good work they are doing by sending the names of such societies as they may know of, and the addresses of their principal officers, to Mr. Charles A. Jenney, Special Agent of the Eleventh Census, 58 William street, New York City.

Cruelty to the Insane.

Dr. Henry M. Wetherill, Secretary of the State Committee on Lunacy, has addressed a letter to the physicians in Pennsylvania, in which he says:

In view of the fact that in the past instances have occurred in various parts of this State of cruel or improper treatment of insane persons in charge of private parties, and that through the aid of physicians and others the Committee on Lunacy were enabled to extend material relief to such insane persons, and for the purpose of ascertaining whether any such cases exist at the present time to whom assistance might be rendered, the Committee would ask again for information of any insane who are secluded, badly treated, or require hospital care and treatment. The Committee will, on information, investigate any such case. Any communication will be, if desired, considered as confidential.

Dose of Tincture of Nux Vomica.

Mr. Jonathan Hutchinson (*Archives of Surgery*, Jan., 1890, p. 280) says he has for many years prescribed the tincture of nux vomica very freely indeed. He thinks it the best of all tonics, for it very rarely disagrees, and he has never known it to produce poisonous effects. He generally gives 10 minims three times a day to an adult, but often double that dose. He has given 5-minim doses to a child of ten, and has, for experiment, taken himself a single dose of 30 drops and realized no symptoms of strychnia poisoning whatever.

He believes the tincture of nux vomica to be a safer and more convenient form than any of the solutions of strychnia, and it has also the advantage of not exciting alarm in the patient. He says it may be taken for months together, and does not diminish in efficiency. Mr. Hutchinson has had many patients who have taken more than was intended and yet never so far with any serious ill result.

He relates two cases. A gentleman, 33 years old, took by mistake five consecutive doses of forty minims three times a day instead of ten minims during the same time, as ordered. The only ill result was that the head had been made to feel dull and the eyes heavy, as if he had been drunk over night. There was no muscular twitching.

In the second case the patient took forty minim doses of the nux vomica tincture. He continued it three times a day for four doses in succession. The symptoms were exactly as in the other case—a dull feeling in the head but no twitchings. He felt "wonderfully better for it." — *Medical Chronicle*, March, 1890.

Paracresotinate of Soda.

Paracresotinate of soda, a new antipyretic, is a fine crystalline powder and has a bitter although not unpleasant taste. It is soluble in twenty-four parts of hot water, and is not precipitated when the water becomes cold. According to the *Journal de Médecine*, March 23, 1890, doses of forty-eight to sixty grains produce no ill-effects upon healthy animals. Free perspiration is usually caused by it, but otherwise no effect upon the digestive functions or upon the temperature is noted. In about half an hour after its administration the urine will assume a violet hue, due to the action of chloride of iron, which may be traced in the urine for thirty hours. Paracresotinate of soda has been used in various febrile diseases incident to childhood, and in every case the drug proved itself of unquestionable value as a reliable antipyretic. Its action was especially beneficial in cases of acute gastro-intestinal catarrh, occurring in very young children. The following formula is recommended:

℞ Paracresotinate of soda . 15 to 30 grains.
Laudanum . . . . . 2 to 4 drops.
Cognac . . . . . 16 minims.
Simple syrup . . . . . 1½ fluid drachms.
Distilled water . . . . 7 fluid drachms.
Mix and give one teaspoonful every two hours.

As an antipyretic fifteen-grain doses given three times, one hour apart (for a child of twelve), would cause a fall of temperature of two to two and one-half degrees Fahrenheit within two to four hours.

Suture of Arterial Wounds.

Dr. Jassinowsky has published, as a graduation thesis in Dorpat, a series of experiments, made on animals, for the purpose of determining the conditions under which it is possible to stitch successfully wounds in arteries. He operated on horses, calves and dogs. The plan adopted was to dissect down to the artery, to open the sheath, and, after applying a clamp to the vessel, to stitch the wound with silk, the needle passing through the external and middle coats only; a reef knot was then tied, and the ends cut off close. When the clamp was removed the vessel was compressed, and all the fasciæ and skin incisions carefully stitched with interrupted sutures. The external wound was then sealed by means of photoxylin, a substance which, though first used by photographers, has recently been introduced into surgical practice as an improvement on collodion for sealing wounds. In all the cases operated on the wounds healed satisfactorily. When viewed from within, an arterial wound that has been recently sewn appears as a fissure of the intima filled up with blood-corpuscles, which form a minute thrombus, causing the sulci of the intima to disappear. Later on a cross section through the sulci gives the appearance of a funnel-shaped space filled with a homogeneous, horny substance. The endothelium is much augmented. In time the whole of

the coats at the wounded spot become thickened, and the elastic membrane is not to be found. Dr. Jassinowsky concludes that wounds not extending beyond half the circumference of a large artery, also longitudinal and oblique wounds, may be successfully sutured if antiseptic precautions can be thoroughly carried out, as was the case in all his experiments. When the vessel lies very deep, however, it is impossible to get at it sufficiently well to practice the delicate manipulation required in the operation. Of course, after a wound has occurred, the sooner operative measures are undertaken the better. He calls attention to the peculiar blowing or rasping systolic murmur always heard over a wounded artery, and the thrill which is perceptible to the touch, which constitute what is known as "Wahl's phenomenon," a discovery made by the eminent Dorpat professor, lately deceased, as a valuable diagnostic sign in cases where it is possible that arteries may have been wounded. —*Lancet*, Feb. 22, 1890.

Hydrophobia.

It is reported in the newspapers of June 2, that a farmer living near Petersburg, Lancaster county, Pa., died from hydrophobia on Saturday after two days' illness. He was bitten by a dog two months ago.

Seven children were bitten by a dog at St. Joseph, Illinois, May 29, and the dog died in a convulsion a few minutes later. The telegram recording the facts adds that "a madstone was applied to each of the children's wounds, and it adhered in each case." Notwithstanding this the patients were sent to New York to be treated by Dr. Gibier in the Pasteur Institute there, and they arrived in New York June 2.

NEWS.

—Dr. George H. Rohé has removed to No. 18 West Franklin Street, Baltimore, Md.

—Dr. James A. Henshall, of Cincinnati, has been appointed a Fish Commissioner for Ohio.

—Dr. John Aulde announces that he has severed his connection with the Medico-Chirurgical College, of Philadelphia.

—Dr. Kate W. Baldwin, a graduate of the Woman's Medical College, has been elected Resident Physician in the Philadelphia Polyclinic Hospital.

—According to the census of 1881, there were 131,618 lepers in all India. It is estimated that there must now be over 200,000 lepers in that country, most of whom are at large.

—The Charing Cross Hospital, London, was the site of a conflagration, May 4. Nobody was injured, and the damage, which was slight, was confined to the Victoria Ward.

—The University of Florida was founded May 30 at Tarpon Springs. Among the incorporators are Hamilton Disston, Jacob S. Disston, A. P. Stafford, F. H. Davis and Dr. Charles E. Sajous.

—On May 29, 1890, the Pennsylvania School for Feeble-Minded Children, at Elwyn, Pa., held its thirty-seventh anniversary. A new building was opened, which will accommodate 120 children.

—The medical faculty of the newly-founded University of Lausanne consists of seven ordinary professors, each of whom is to receive a salary of from 4,000 to 5,000 francs ($800 to $1,000), together with students' fees.

—It is reported that leprosy has increased to such an extent in Cape Colony, that a hospital for lepers has been founded on Robben Island near the African coast. In India legislation is urgently demanded for the suppression of leprosy.

—A committee has been formed at the Sorbonne for encouraging foreigners to study at the University in Paris. M. Pasteur is president. It is proposed to give special facilities to foreign students immediately on their arrival in Paris.

—A death has taken place at Tunbridge Wells, England, following the use of chlorodyne. The coroner's jury rendered a verdict of death by "misadventure," at the same time recommending that the sale of such powerful patent medicines be "restricted."

—It is said that Dr. A. G. Young, Secretary of the Maine State Board of Health, was recently suffering from a disease which had baffled his physicians, one of whom finally sent a sample of the wall-paper from the sick-room to a chemist for analysis. The examination revealed that the paper contained large quantities of arsenic. Since Dr. Young's removal from this room his recovery has been rapid.

SPECIAL and RELIABLE FORMULÆ for PHYSICIANS' PRESCRIBING

The Coating will Dissolve in 4½ Minutes.

PIL. SUMBUL COMP.
(Wm. R. Warner & Co.)

(DR. GOODELL.)

℞—Ext. Sumbul.....1 gr. | Ferri Sulph. Ext.....1 gr.
Assafœtida.....2 gr. | Ac. Arsenious.....1-30 gr.

"I use this pill for nervous and hysterical women who need building up." This pill is used with advantage in neurasthenic conditions in connection with Warner & Co.'s Bromo-Soda, one or two pills taken three times a day.

PIL. LADY WEBSTER.
(Wm. R. Warner & Co.)

℞ Pulv. Aloes.....2 gr. | Pulv. Rose los.....½ gr.
" Mastic .....½ gr. | M. ft. one pill.

Lady Webster Dinner Pills. This is an excellent combination officially designated as Aloes and Mastich, U. S. P. We take very great pleasure in asking physicians to prescribe them more liberally, as they are very excellent as an aperient for persons of full habit or gouty tendency when given in doses of one pill after dinner.

PIL. ALOIN, BELLADONNA, AND STRYCHNINE.
(Wm. R. Warner & Co.)

℞—Aloin, 1-5 gr. Strychnine, 1-60 gr. Ext. Belladonna, ⅛ gr.

Medical Properties—Tonic, Laxative. Dose, 1 to 2 Pills.

Try this Pill in habitual constipation.

PIL. ARTHROSIA.
(Wm. R. Warner & Co.)

FOR CURE OF RHEUMATISM AND RHEUMATIC GOUT.

Formula.—Acidum Salicylicum; Resina Podophyllum; Quinia; Ext. Colchicum; Ext. Phytolacca; Capsicum.

Almost a specific in Rheumatic and Gouty Affections.

PIL. CHALYBEATE COMP.
(Wm. R. Warner & Co.)

Same as Pil. Chalybeate, with 1-6 gr. Ext. Nux Vomica added to each Pill to increase the tonic effect. Dose, 1 to 3 Pills.

PIL. DIGESTIVA.
(Wm. R. Warner & Co.)

A VALUABLE AID TO DIGESTION.

℞—Pepsin Conc't.....1 gr. | Gingerine.....1-16 gr.
Pv. Nux Vom.....¼ gr. | Sulphur.....⅛ gr.
IN EACH PILL.

This combination is very useful in relieving various forms of Dyspepsia and Indigestion, and will afford permanent benefit in cases of enfeebled digestion, where the gastric juices are not properly secreted.

As a dinner pill, Pil. Digestiva is unequalled, and may be taken in doses of a single pill either before or after eating.

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

CLINICAL LECTURE.

REMOVAL OF UTERINE APPENDAGES.—TWISTING OFF A FIBROID POLYPUS.—FIBROID TUMORS.

BY E. E. MONTGOMERY, M. D.,
PHILADELPHIA.
PROFESSOR OF GYNECOLOGY, MEDICO-CHIRURGICAL COLLEGE; OBSTETRICIAN TO THE PHILADELPHIA HOSPITAL.

Removal of Uterine Appendages.

Gentlemen: From this patient I removed the uterine appendages in this amphitheatre one week ago; I removed the sutures yesterday, and found the wound had united perfectly by first intention. The result in a private hospital could not have been more satisfactory. The temperature has at no time since the operation gone up higher than 100.2° F., and for these delightful results I feel that I cannot too highly commend the antiseptic precautions that were exercised in the preparation of this room, the attention to details during the operation, and the faithful care of the Resident Physician and the nurse in the after treatment.

Twisting off a Fibroid Polypus.

The patient whom I bring before you today is forty years old. Her father died of pneumonia. She has two children. The elder is living, and the younger died when he was five years old. She denies any venereal history. Some years ago she fell down a flight of twelve steps and at her next period she flooded, and from this time there began a very perceptible development in the size of this umbilical hernia. Since then she has often had severe uterine hemorrhages, or excessive menstruation. This is greatly increased by any exertion. Ten days ago she took cold and had pain in her abdomen. She came here about the fifth day of her illness. The pains were differentiated from labor pains because they were continuous and

not periodic. Examination disclosed a mass protruding into the vagina from the cavity of the uterus and she had a profuse discharge which was quite offensive. The temperature went up, at once, to nearly 109° F., and stayed at that point. This mass, protruding into the vagina, has been rapidly increasing in size. The neck of the uterus encircles the circumference of the tumor. Its character is hard to determine from conjoined manipulation, because the patient is so fat. To arrive at a correct diagnosis we must summon to our minds the diseased states which are likely to produce such symptoms. These conditions would be either a submucous uterine fibroid or an inversion of the uterus.

There is no reason to believe that this is a part of a placenta or of the product of conception, so that such an idea can be dismissed at once from our minds. Inversion of the uterus may occur as a result of parturition. A woman in labor may, when the cord is dragged upon in order to deliver the placenta, suffer inversion of the uterus. This accident used to be comparatively common in the days of midwives, or when the placenta was delivered by traction on the cord. Again, inversion may result from a growth in the fundus or at either angle of the uterus. The dragging down which such a growth would cause results in an inversion of the womb. Therefore, always examine everything carefully. From a sarcoma of the uterus the muscular walls of the organ may lose their tonicity, so that there may be left no power to resist the tendency to inversion.

The question that is now asked is: How is one to find out when the uterus is really inverted? First, by conjoined manipulation which would show a cup-like depression instead of the rounded top of the uterus. If this method fails, supplement it by rectal examination, and, in order to impress its importance upon you, I shall relate to you the following example. A friend of mine who had had a large experience was called to see a woman who had a large mass protruding from the uterus into the vagina. Conjoined manipulation disclosed a depression at the normal position of the fundus uteri. It was diagnosed inversion. The consulting physician attempted to get the organ back in position by introducing his finger into the cup-shaped depression through the rectum, his purpose being then to draw down upon the womb while the other hand in the vagina pushed the displaced body of the organ back into position. But he was surprised to find that his finger passed over a retroverted uterus, which a preliminary rectal examination would have disclosed.

The cup-like depression he felt in front was due to the traction of the pedicle of a fibroid polypus attached to the anterior wall of the uterus, while the tumor hung in the vagina. Therefore, let this example impress upon you that you should always examine through the rectum, especially to reach the posterior part of the uterus.

I now introduce my finger and find that the mass fills up the vagina pretty well. I next pass my finger well into the uterus and pass it well around in that organ. The pedicle of the tumor becomes smaller as I get nearer to its base. This might be due to a constriction by the neck of the womb. But the facts that she has hemorrhage, comparatively good health and a tumor, indicate to me that she has a fibroid growth.

The next question is: How is this fibroid tumor to be removed? The pedicle may be either large or small. If the base be broad, it is called a sessile tumor; if the base be small, it is called a polypus. In case of a tumor like this the method of its removal depends on the size of its base. If the pedicle is small it can be twisted off. Here it can be seen that the tumor is sloughing. If I had not been wanting to show it to you, I would have removed it yesterday. This it is, that has been the cause of such high temperature. It is so fragile that when I try to get a good hold on it with my volcellar forceps it easily crumbles under the pressure. But finally I do obtain a good hold and after a few twists the tumor comes off. Its weight is about twelve ounces.

Fibroid Tumors.

Fibroid tumors may be divided, histologically, into the following varieties: first, the soft fibroid, in which the muscular tissue predominates, hence called myomata. The tissue is similar to that of the uterus, and presents no line of demarcation. The growth is rapid, sometimes attaining to enormous size.

Second, the hard fibroid, in which the fibrous tissue predominates. The tumor grows slowly or is stationary and is completely surrounded by a capsule. All fibroid growths originate in hypertrophy of the uterine muscular tissue as a result of local inflammation.

The tumors are divided, according to situation, into: first, submucous, situated

beneath the mucous membrane. In these hemorrhage is a marked symptom, owing to the obstruction of circulation in the uterine mucosa. Second, mural or interstitial, when hemorrhage is also a marked symptom, particularly when the tumor protrudes upon the cavity of the organ. Third, subperitoneal; the tumor in its growth being forced out of the uterus beneath the peritoneum. The same uterus may present all the varieties of fibroids and they may vary in size from that of a cherry to growths exceeding one hundred pounds in weight. The symptoms vary according to their locality. The nearer they are to the mucous surface, the greater is their hemorrhage. A very small tumor in the cavity of the uterus will frequently give rise to frightful hemorrhages.

The following instance will exemplify this principle. A woman suffered from frequent hemorrhages during the last two years. The uterus felt irregular and nodular, and I thought that malignant disease was present; yet the trouble was not in the cervix, but in the body of the womb. As it was late in life, I feared the worst, so that I did not dilate the cervix and examine into the cavity of the uterus, but I took out the uterus itself and, to my surprise, I then found that the hemorrhage had been due to a small fibroid tumor, no larger than a marble, situated near the fundus. There was, however, a fibroid degeneration of the uterine walls, so that later she would have suffered from a return of the bleeding, and in time would have had to undergo some operation for its arrest. She is now doing well. The substance obtained from the endometrium by curetting should always be examined under the microscope.

When we meet with fibroid tumors of the uterus how are they best to be removed? First, when the tumor is submucous it would be best grasped with a pair of stout polypus forceps, drawn down, and then twisted off; provided its base be not too broad. This is the best method in ordinary cases, as by the twisting we are most apt to get off all the tumor and less apt to cause bleeding; second, a wire ecraseur with a good stout single wire may be thrown around tumor's pedicle, whether it be large or small; third, the tumor may be well drawn down, and then its pedicle clipped with a pair of curved scissors. This method is applicable when the base of the tumor is small.

Some years ago I met a patient who had been treated for two years, for hemorrhage without success and, what is more serious, without an examination. I thoroughly examined her, and after splitting up the cervix on either side to the lateral fornices, enucleated from her uterus a fibroid tumor by means of my finger and a Thomas's spoon-curette. It was about the size of a hen's egg, and after it was separated from its bed it was with difficulty delivered through the narrow internal os. When the tumor is too large to remove entire it may be cut away in pieces.

A mural tumor may cause a patient long suffering before the walls of the womb become thick enough to admit of its separation. The old plan of cutting down through the capsule, and then giving ergot, exposed the patient to gangrene and blood poisoning. A better plan is to split up the cervix, and then enucleate the tumor with the fingers and a spoon-curette.

COMMUNICATIONS.

IS CONSUMPTION CONTAGIOUS?[1]

BY THOMAS J. MAYS, M. D.,

PROFESSOR OF DISEASES OF THE CHEST IN THE PHILADELPHIA POLYCLINIC.

Mr. President: In casting a retrospect over the two years which have passed since our last meeting I am quite certain that you will agree with me when I say that the task of reviewing in a short address all the work which has been done in the name of hygiene during this time would be a prodigious if not a profitless undertaking, and that you will pardon my confessed inability to fulfil the strict letter of the law if I confine my remarks to the consideration of a special department of this branch of medicine, and thus make an effort to compensate in concentration that which I lack in generalization.

The theme to which I shall invite your attention to-day is that of *The Relation between Artificial Inoculation and Pulmonary Consumption.* The study of pulmonary consumption, like that of cholera, yellow fever, leprosy and many other diseases, has been approached from two directions—(1) from the experimental or laboratory side, and (2)

[1] The Address in Hygiene, delivered before the Pennsylvania State Medical Society, at Pittsburgh June, 1890.

from the clinical side. It must be admitted on every hand that these are legitimate and scientific methods of investigation; and, whatever the nature of their results may be, one thing is perfectly clear, and that is, that being the products of genuine processes, they corroborate each other, and must hence be accepted. Under such circumstances one side cannot be absolutely and entirely right, and the other absolutely and entirely wrong, but both must be entirely right, and must be complementary to each other. What then has each method contributed to the study of this disease?

In 1865 Villemin produced tuberculosis in rabbits by inoculating them with tuberculous material. This has since been abundantly confirmed by other observers, and in 1882 Koch gave the study of tuberculosis a fresh impetus by demonstrating that a specific micro-organism—the tubercle bacillus—is associated with the tubercular virus. When this organism is injected subcutaneously into the bodies of animals tuberculosis is generated. Tuberculosis may also be induced by feeding tubercle virus to animals, or by compelling them to inhale the same. It must be stated, however, that artificial tuberculosis is most readily induced by the first, and least readily by the last two methods. Rabbits and guinea-pigs are more susceptible to it than cats and dogs, and on the whole the disease seems more communicable when the virus is introduced into the abdominal cavity than into the eyeball.

These facts show very conclusively that tuberculosis is transmissible from man to animals through inoculation, and they have naturally given rise to the almost universal belief that pulmonary consumption is a contagious disease. The health authorities of the State of Pennsylvania and of a number of the large cities of this country and of Europe have been moved to adopt measures which have in view the suppression of this disease on the score of its contagiousness.[1] By common consent it must be admitted that this is a serious matter; for if this belief is correct these officers are discharging a most sacred and responsible duty, in which they should receive the encouragement of every loyal citizen. If it is erroneous it is equally clear that these officials not only perpetrate a terrible wrong on those who are afflicted with this disease, but also waste the time and energies of the people by misleading them in regard to the true nature, cause and prevention of consumption.

Let us see, then, whether clinical medicine is able to throw any light on the truth or falsity of the contagion doctrine. In discussing this side of the question I will start out with the fundamental and self-evident proposition that, if other things are the same, those who are most exposed to a contagious disease are most liable to contract it. This may be very aptly illustrated by some of the accidents due to railway travel. While only a portion of those exposed to railroad accidents are injured or killed, it still remains true that the mortality rate from such casualties is higher among those who travel in cars than among those who do not. This principle holds true in the case of small-pox, measles, etc., and is the *experimentum crucis* in the case of consumption, if, like them, it is a contagious disease. Now those who hold to the contagion doctrine say that the tubercle bacilli are the elements on which the contagiousness of consumption depends—*i. e.*, they are the carriers of the disease from person to person. It has been demonstrated that these germs abound in localities where the disease exists, and are absent where the disease is not found. Such localities are hospitals for consumption and the homes of those who suffer from the disease. It is inevitable, therefore, that physicians, nurses and attendants of consumption hospitals, and intimate relatives of consumptive patients are more subject to the disease than those who are but seldom exposed. What are the facts?

Physicians who are constantly exposed to consumption are much less subject to it than are butchers, coopers, locksmiths, etc., who scarcely come in contact with it except by chance. The statistics of the Bumpton Hospital for Consumption, in London, show that during a period of thirty-six years not a single clearly-authenticated case of consumption arose within its walls among its twenty-nine physicians and assistant physi-

[1] The Board of Health of the State of Pennsylvania in a recent circular (No. 26, page 6) says: "Painful as the conviction that he is liable to be a dangerous source of infection to his family and friends, as well as to the public, must be to the sufferer from phthisis, it must be forced upon him. This is the duty of his medical adviser." Further precautions given are that under no circumstances shall his expectoration be allowed to dry before it is destroyed, and that he must scrupulously avoid spitting on his handkerchief, on the floor, or on the ground, and instead must use a small spitting-flask.

cians, its one hundred and fifty clinical assistants and its one hundred and one nurses, of which there existed a health record. The statistics of Friedrichshain Hospital, in Berlin, recently gathered by Dr. Fürbinger, show that during a period of sixteen years out of 459 male nurses there were 4 (two of whom were tuberculous before entering); of 339 female nurses there were 2; of 83 physicians there were 3 (one of whom entered with the disease) who became consumptive. Of 108 Victoria sisters, who were engaged as nurses in the same institution from two to five and a half years, only one became consumptive.

These statistics are also strikingly confirmed by those which show the influence of the Consumption Hospital of Görbersdorf, in Germany, on the death-rate from phthisis among the inhabitants of that town. Dr. Brehmer, who had been in charge of that institution for twenty years, says that since the year 1854 more than ten thousand consumptives resided in the hospital, who daily walked the streets of the town and commingled with its inhabitants. The latter were, therefore, continuously respiring an atmosphere more or less laden with tubercle-bacilli emanating from the dried expectorations of these consumptive visitors; yet, in spite of these favorable conditions for contagion, the mortality is 50 per cent. less among the Görbersdorf population since than it was before the establishment of the hospital. These figures are especially interesting in view of the assertions frequently made that the healthful influence of mountain resorts is impaired by the infectiousness of the exhalations and expectorations coming from consumptive people who go there for relief.

Then, again, it may also be said that it is not true, as is so often asserted, that the attendants of hospitals, where other diseases than consumption are treated, enjoy a similar immunity from disease. This is well shown, at least so far as typhoid fever is concerned, in the records of the Massachusetts General and the Boston City Hospitals. In the former, from 1882 to 1887, no less than seven, and probably eleven; and in the latter, from 1884 to 1888, twenty-eight cases of typhoid fever occurred among the medical attendants and employees of these institutions.

Similar negative testimony is obtained from the statistics of the contagiousness of consumption between husband and wife. Dr. Schnyder, of Switzerland, gives a record of 844 cases of consumption occurring among married people. In 445 of these the husband only, and in 367 it was the wife only was consumptive, while in thirty-two both husband and wife were affected: showing that in 812 instances there was not the least proof of contagion. Is there any reason to believe that the disease originated through contagion in the 32 cases? Dr. Schnyder says not, for four of these cases came to him fresh from the matrimonial altar affected with the first signs of consumption, and he is of the opinion that in spite of all warnings, young people are frequently married while suffering from the disease. The late Dr. Flint gives the history of 670 cases of consumption which affected husbands and wives, and among these there were only five in which there was a suspicion that the disease might have been contracted from one or the other; but it is certain, he says, that the instances in which transmissibility may be suspected can also be accounted for as coincidences in a disease which is so prevalent as consumption. M. Leudet shows, too, that out of 112 widows and widowers, whose consorts died of consumption, only 7 (four women and three men) became phthisical; hence there remained 105 who lived intimately with tuberculous people without contracting the disease.

About seven years ago a committee of the British Medical Association distributed circulars of inquiry among the members of the profession in regard to the liability of contagion between husband and wife or between members of the same family, etc. Ten hundred and seventy-eight answers were received. Of these 778 were negative, 39 doubtful, and 261 were affirmative.

The large number of affirmative answers which have been received in this investigation are taken as proof of the contagiousness of this disease. This evidently is a mistake, for the aim of the inquiry was not to ascertain the number of absolutely well-demonstrated cases in which contagion was present or absent, for this would obviously have been an impossibility, but it was to collect the individual opinions of a large number of physicians as to whether they believed the disease to have been contagious in certain cases or not; and this resulted in 778 negative and 261 affirmative votes. Are we to assume, therefore, that the 261 opinions are of more weight than the 778 nega-

tive ones, and thereby imply that the former only had the fortune or misfortune of meeting cases which originated through contagion, and the latter had not? Is it not more probable that all of them witnessed cases around which hung a cloud of suspicion that they might or might not be contagious, but that 778 did not consider the proof strong enough to outweigh that which, in their minds, was in favor of other and more powerful influences in the causation of the disease?

Now, in converging the evidence of the two sides of this question there appears to be an irreconcilable contradiction. The experimental testimony points decidedly towards contagion, while the clinical testimony just as decidedly opposes such an opinion. It must be remembered, however, that the first kind of evidence pertains only to experiments on the lower animals, and, in so far as it applies to the human body, rests entirely on a theoretical basis. It establishes the fact, however, that when the tuberculous virus is introduced under the skin tuberculosis follows. On the other hand, clinical evidence utterly fails to show that such inoculation occurs in practical life; nor does it show that those who are most exposed to the bacillus tuberculosis, as it is disseminated through the atmosphere, or through food, are more, or as much, liable to contract the disease as those who are not so exposed.

When the apparent antagonism between these two kinds of testimony is thoroughly sifted it will be found that, so far as the origination of pulmonary consumption is concerned, laboratory experiments are absolutely silent. All that they show is that the disease may be transplanted by a certain method after it has been called into existence by other causes. Clinical medicine does not, perhaps, define the exact mode of the origin of consumption, but it positively asserts that it does not arise by being transmitted from person to person through contagion. The great difficulty in the discussion of this problem has always been a neglect to distinguish between the origin and the transplantation of consumption. These two phenomena are actually treated as if they were one and the same thing, yet the original genesis of a new form of life, whether normal or abnormal, differs as much from the artificial transplantation of the same as sunlight differs from moonlight.

The truth of this is strikingly illustrated in skin grafting. Particles of skin are planted on denuded surfaces and become thoroughly incorporated with the bodily tissues, yet such an artificial procedure gives us no knowledge of the origin and mode of genesis of the skin that is transposed. In cow-pox vaccination—another example of the same kind—a new form of life is not only transplanted to the body, but the new form of life has a deep, modifying influence on the whole organism; yet neither the operation nor its products gives us the remotest idea as to the source of the virus against the action of which it protects the body. Another exemplification of this is found in the vegetable kingdom. It is well known that a graft is capable of communicating the peculiar properties of the fruit, color of leaves, etc., of the tree or plant from which it is taken, to the whole tree or plant on which it is grafted.

Dr. Darwin, after relating a number of cases in which grafting or budding of the variegated jessamine, the oleander, and the ash, infused their peculiar characteristics into the stocks which received them, states[1] that "many authors consider variegation as the result of the disease; on this view, which, however, is doubtful, for some variegated plants are perfectly healthy and vigorous, the foregoing may be looked at as the direct result of the inoculation of a disease." Dr. Masters, in an able contribution to the subject,[2] says: "Cases have been observed where, from the stock *below* the graft, fruits and flowers of the same appearance as those borne on the scion have made their appearance. This has been observed in the case of the pear grafted on the mountain ash, and in other cases." In regard to the transmission of variegated leaf properties through grafting, Dr. Masters states that "a year or two since a beautiful *Abutilon*, with leaves mottled with yellow, was introduced into our garden. It was very desirable that this should be propagated as largely and as speedily as possible. The scions of the variegated *Abutilons* were grafted on to green-leaved stocks of other *Abutilons* by many nurserymen on the Continent and in this country, and it was soon found that the grafted plants produced variegated leaves from the stock. That the variegation is really due to the influence of

[1] Animals and Plants under Domestication, Vol. I, p. 474.

[2] Grafting: its Consequences and Effects, *Popular Science Review*, April, 1871, p. 149.

the scion is shown by the fact that if the graft becomes separated from the stock, the leaves subsequently produced from the latter were wholly green, as before the grafting, and even the variegated leaves originally produced lost their mottled character."

Let us then for a moment imagine the feelings of the experimental physiologist whose mental vision of the source of plant-life is limited to a knowledge that grafts have the power of infusing the peculiar color of their leaves, the nature of their fruit, the odor of their flowers, and their very fibre and constitution into the stock upon which they are grafted, on being ushered into a beautiful grove of trees, or into a garden of flowers. Would he not in his ecstasy at once say to himself, it is clearly demonstrated that grafts possess the power of transmitting these properties to the plant-stock, therefore it must follow that all this diversified wealth of vegetable form and beauty is the product of inoculation by grafting? Would not his analysis be as wise and as justifiable as that of the experimental pathologist who announces that because pulmonary consumption may be occasioned by artificial inoculation, nature pursues a similar course in producing the disease? I do not by any means ascribe to myself infallibility of judgement, but I appeal to you, gentlemen, whether the mental processes employed by both the contagionists and the believer in the creative power of vegetable-grafting, are not entirely identical in nature and in character?

Take away the inoculation experiments on animals and you destroy the corner-stone on which those who believe in the communication of consumption from man to man repose their belief. I am not unmindful that there are many who deny this, and who claim that their faith rests on certain and well-defined evidence of contagion. But I never yet saw a case of this kind reported which on thorough examination did not turn out to be a case of misplaced confidence, so far as positiveness is concerned. Probability exists sometimes, but this does not constitute positive proof. Nor need any one wonder at this, for it is not a question which is susceptible of decision by an appeal to specific individual instances, either for or against contagion, as has been maintained throughout this paper. But it is, as Dr. Oldendorff has recently expressed it, in a discussion of this same subject before the *Verein für Innere Medicin* in Berlin, a question which must be determined by statistics; and statistics, as we have seen, give no uncertain tone in response.

When direct statistical evidence, such as that submitted in this paper, shows that among one thousand six hundred and twenty-six married persons, where consumption existed either in the wife or in the husband, only the same disease occurred in the other partner in only forty-four instances, the certainty of non-contagiousness is placed beyond the shadow of a doubt. Here we have the picture of more than 1,600 people who were subjected to a much closer intimacy than that which obtains in any other condition of social life, occupying for years the same bed at night and the same room by day, and yet only forty-four or 2.73 per cent. of the consorting partners became fellow-sufferers. Truly, if consumption is contagious, it can only be so in a very slight degree. But can the source of these forty-four cases be traced to infection? Hardly, for in a disease which is as general as consumption, it is highly probable that many of them carried within their systems a tendency to the disease, which only awoke out of its slumbering condition and asserted its power when the many varied burdens and demands of family life began to exhaust the vital resources. Again, it may be true, too, that some suffered from an active or a latent form of the disease before they were married. Indeed Dr. Schnyder, who contributes the largest number of these cases, states distinctly that four of them came to him fresh from the matrimonial altar, victims of the disease in its incipiency.

Moreover the contagiousness of consumption is an old idea, and all the measures of prevention which are receiving serious consideration from those who believe in it at the present time were tested with disastrous results by the inhabitants of Naples more than a hundred years ago. They reasoned as follows: If consumption is contagious, then the separation of the afflicted from the well is the only logical remedy, and for sixty-six years—from 1782 to 1848—they enacted and enforced the most rigorous laws that have ever been introduced for the suppression of any disease. Every physician was fined $180.00 for the first neglect to report a case under his observation, and was banished for ten years for the second offense. In every case the ceilings, walls, floors, doors and windows of the rooms in which consumptives died were torn out, and burned,

and new ones were substituted. The bedding and furniture shared the same fate, and such dwellings were not inhabitable for one year. In consequence of these stringent laws the family with consumption in its midst was shunned and driven to want, and the patient was regarded as a public pest. Houses in which consumptives died came into disrepute, and many of their owners were turned into beggars. The sick were neglected and left to die inhumanly away from their families and friends. The intolerance of all this heroic treatment becomes more evident when we find that it had no influence whatever in diminishing the death-rate from this disease in Naples, and in other localities where it was administered. But, however much these colossal and outrageous crimes, performed under the cloak of justice and of humanity, may shock us, they demonstrate how earnestly the Neapolitans believed in the contagiousness of consumption. If they failed to suppress it, how much can the modern contagionists expect to accomplish by requiring that consumptives should cease to spit on floors, ground and pavements, and use fixed or portable spittoons instead. Indeed, when this advice is compared with the resolute and vigorous efforts of the unfortunate and deluded Italians, it seems more like the vaporings of a child's brain than the outcome of thoughtful and sober reflection; and it is sad to find men at this late day who are willing and anxious to repeat the superstitious follies and foibles of a century ago.

From all that has been said it seems perfectly plain to me that pulmonary consumption is not contagious in nature, and that its genesis has nothing whatever in common with that of small-pox, wound fever and other diseases which arise through infection. The works of Villemin, of Pasteur and of Koch have vastly enriched the science of experimental pathology, but they have absolutely no bearing on the natural origin of pulmonary consumption or on the question in dispute. No theory of any disease can be true unless it also points out the path of prevention and alleviation of that disease. Has the bacillus theory, which is so popular at the present day, rendered any such service to medical science? Has it lessened the mortality rate of this disease in the past, or does it give any assurance of doing so in the future? Can any one claim that it has not been accorded a fair and generous hearing? Was ever a medical theory launched under more favorable auspices, or received with greater enthusiasm? The medical profession, prompted by the hope, long deferred, that a knowledge of the tubercle bacillus would accomplish for phthisis what the germ idea had done for practical surgery, eagerly and frankly accepted it, and thoroughly proved it; yet he who takes a calm and impartial retrospect of the whole situation must own that never was an *ignis fatuus* pursued which left more promises broken and greater anticipations unfulfilled than this bacillus theory, so far as it stands related to the prevention and treatment of pulmonary consumption.

FUNCTIONS OF THE SPLEEN.

BY N. M. GEER, M. D.,
JEDDO, OHIO.

The functions of the spleen is a subject concerning which there has been much discussion and many theories have been advanced in regard to it; none of the theories, however, having stood the test of physiological investigation. Any statement, therefore, that one may make on the subject will doubtless be received with caution and subjected to a rigid scrutiny before being accepted. This I expect; and I only ask the reader to approach the subject in a spirit of fairness, and to give due weight to the evidence advanced. I shall endeavor to establish my position by means of facts known and accepted by the medical profession.

I will first make a general statement, that the spleen is a temporary depot, or place of deposit, in which certain excrementitious and waste products of the system are stored until they can be removed from the system by the proper organs; or, in the case of materials not excrementitious in character, reappropriated in another form. Incidentally to the above, it is a place in which red blood corpuscles undergo disintegration and white blood corpuscles are formed.

That the spleen has important functions cannot be doubted; its large size, complex structure and abundant blood supply precluding any other idea; for nature does not deal in superfluities, and the organ for which there was no use would soon, like the alveolar process from which the teeth are extracted, atrophy and disappear. The utility of the purposes above named will also be apparent; for, in the varying conditions of

life, the truly excrementitious principles are frequently produced in quantities which can not at once be eliminated from the organism, the process of elimination being slow. It is, therefore, a wise provision of nature that these materials should be temporarily removed from the general circulation, where they might do much harm, and placed in a proper receptacle where their presence will be innocuous or at least *less* harmful than elsewhere.

But in what manner is this done? Presuming that my readers are all medical men and anatomists, I will not go into anatomical details, but content myself with the statement that the blood in the spleen flows from the smaller arteries to capillaries, and from the capillaries into minute spaces formed by branching endothelial cells. Here it comes into immediate contact with the spleen pulp.

In this soft and sticky mass the blood is rid of certain materials. All substances in imperfect solution are filtered out, as it were; and doubtless many others are removed by chemical changes and combinations, which we do not understand definitely as yet, but which offer a favorable field for future investigations. Red blood corpuscles, also, which are of a low grade of vitality, stick fast here and undergo disintegration. The red blood corpuscle has doubtless, like other anatomical elements, a certain limited period of existence. When this is fulfilled, it perishes in the spleen. It is not, as formerly stated, destroyed there, but merely perishes there from lack of vitality. For some of these latter statements I claim no originality, these facts having been demonstrated and announced by Frey, Stowell and other histologists. A similar opinion seems also to have been held by Austin Flint, judging by statements made in his work on the *Practice of Medicine.*

What evidence have we that our statements are correct? The amount of various chemical ingredients contained in the blood of the splenic artery, as compared with that of the splenic vein, is found by numerous experiments to vary considerably, the greater quantity of the given element being sometimes contained in the artery and sometimes in the vein. This shows that these elements are at times stored in the spleen, and again, under different circumstances, taken up and removed by the blood current. The spleen pulp contains at all times most of the excrementitious matters of the body. This is especially true of cholesterine and of uric acid, both of which exist at all times in considerable quantities in this pulp. There is, of course, a variation in the actual quantity of these elements present, as they are eliminated from the system, the former by the liver and the latter (mostly as urates) by the kidneys. The number of red corpuscles in the blood is diminished in passing through the spleen, showing conclusively that some of them cease to exist in their previous form in that organ. In poisoning by chlorate or nitrate of potassium, or by other articles producing a similar injury of red corpuscles, the injured corpuscles accumulate in the spleen. In malarial diseases, while there is some difference of opinion as to the manner in which the blood changes are caused, the fact remains that a destruction or diminution of red blood corpuscles occurs, anemia being present in a noticeable degree in every case in which the disease has any material duration. And we find in these diseases a uniformly occurring enlargement of the spleen.

In septicemia, a disease accompanied by commencing disintegration of red corpuscles, the spleen is enlarged. The spleen enlarges also, in nearly all infectious diseases, in which we have the best of reasons to believe that injury of blood corpuscles occurs.

The facts enumerated seem to me competent to show that the spleen removes from the circulation red corpuscles which are so much injured by any morbid process as to be incapable of continuing to perform their normal functions. The formation of white corpuscles in the spleen may be regarded merely as an incidental circumstance, the materials and conditions for their development being present here in a high degree; and observation teaches us that these bodies are found wherever and whenever the proper materials and conditions exist.

But it has been urged, in opposition to every theory advanced as to the functions of the spleen, that this organ may be extirpated and life be prolonged indefinitely. I reply that, if the principal excretory organs (liver, kidneys, skin) be in a normal condition, they may dispose of the excrementitious principles referred to, with sufficient rapidity to prevent any injurious accumulation of them in the system; and the disintegration of red corpuscles would probably occur also in the adenoid tissues of the body. But the individual who was without a spleen, would, in my opinion, be subject to the development of cholesteremia and uremia, and of

hematogenous jaundice, from causes which would be insufficient to produce the same conditions in a person still possessing a spleen. The observations of cases in which the spleen has been extirpated have been as yet, too limited to settle this point positively.

Much more might be said in support of the views I have just advanced; but, to economize space, I will leave the subject for further investigation at the hands of others, first, however, referring to the practical application of this theory; for, if it has no practical application, our time has been wasted. In all cases in which enlargement or disturbance of the spleen can be ascertained, it may usually be taken to indicate:

1. That there is a disturbance of the action of some excretory organ; or

2. That a morbid process destructive of red corpuscles is occurring.

The remedy would be to restore the action of the delinquent organ, or to stop the morbid process if possible.

UNDECIDED POINTS IN THE ELECTRICAL TREATMENT OF FIBROID TUMORS.

BY G. BETTON MASSEY, M. D.,

PHILADELPHIA.

An increasing experience with the Apostoli method of treating fibroid tumors of the uterus has clearly demonstrated to me its great value; there are, nevertheless, certain important details connected with it yet undecided, the elucidation of which would be of great service to those using the method. We are, for example, yet uncertain as to the relative value of puncture and intra-uterine applications. During the past year I have treated a large number of these cases, invariably with some degree of good result; but I am not yet in a position to lay down hard and fast rules for the selection of either method in a given class of cases. The year's work included two tumors that disappeared completely under the intra-uterine treatment,[1] which, with many other cases of shrinkage and symptomatic cure, has led me to continue to give preference to this form of treatment. One of these cases of complete disappearance by apparent absorption was a large firm fibroid, completely filling the pelvis and extending up into the abdominal cavity. The other case was a mere projection from the right fundus, and was outlined with some difficulty, owing to the thickness of the abdominal walls. Both patients are now not only symptomatically well but absolutely free from growths or enlargements of any kind.

Electro-puncture has been used in several cases that were either of the distinctly subperitoneal variety or had inaccessible cavities, but the number has been by no means sufficient to establish any results capable of a relative comparison; for, although the cases all presented some improvement, several possessed disturbing factors, such as a concurrent syphilitic taint, that impaired the value of the results. Enough has been learned of this procedure, however, to convince me that it is by no means dangerous in careful hands. The procedure that I have adopted has varied somewhat from that laid down by Apostoli. A solid needle is used, which is insulated to within a centimeter of the end, in such a manner that the insulated and un-insulated portions present the same diameter. This permits the burying of the bare part of the needle in the growth and the confinement of the directly destructive action to the morbid tissue. The track of the needle through the overlying healthy tissue having been protected from cauterization, it readily heals by first intention, making the application a submucous one. The value of this form of puncture deserves earnest investigation.

Another point of much importance is the question of dosage. For the intra-uterine applications the most useful range is from 25 to 150 milliampères, with a preference for the lower figures. For puncture by the submucous method, from 100 to 200, with a preference for the higher figures. Beyond these figures the results have not seemed to me to correspond with the increased currents.

The electrical treatment of cystic fibroids is well-known to be inadvisable, unless the value of drainage in connection with the treatment is established; and this introduces the necessity of excluding the presence of cysts in apparently solid tumors. The discovery made at times by operators, that small cysts exist without being suspected, has been used as an argument against an electrical treatment. Through the close

[1] For full details of these cases see *Electricity in Diseases of Women*, 2d edition, pp. 144 and 154.

observation that I have been enabled to make of all kinds of fibroid tumors under treatment in my private Sanitarium, I have discovered that cystic tumors invariably show a diurnal variation of temperature. This variation may be of only one degree, Fahrenheit, but it is in my experience significant of the presence of a cavity in a degenerating fibroid and of the inadvisability of promoting the degenerative process without giving exit to the contents. I have recently punctured and aspirated such a cyst through the anterior abdominal wall with success.

With this exception all forms of uterine fibromata have been demonstrated to be amenable to the Apostoli method; and, as its power to cause complete disappearance of the denser and harder tissue of old cases is naturally limited, I make a plea for the early diagnosis and treatment of this disease —a plea that seeks the restoration of the patient to comfort and health, without incurring danger and with all of her organs and functions intact.

Hysterectomy and oöphorectomy for fibroid tumors I leave to the judgment of those desiring to perform the operation. Only one case in which I have used electricity has subsequently been operated upon: a dispensary patient, who, I am told, only reluctantly consented to the operation instead of seeking it. The result was death on the fourth day after the operation; and this only confirmed in my mind the adverse views that have been expressed of late by many broad-minded men engaged in abdominal surgery.

1706 Walnut Street, Philadelphia.

SUBMUCOUS RESECTION OF CARTILAGE IN DEVIATIONS OF THE NASAL SEPTUM.[1]

BY JOHN B. ROBERTS, M. D.

There are cases in which simple division of the nasal septum, with the use of pins to hold the divided partition properly in place, is not efficacious, because the cartilage contains too much tissue to be held in a straight line after its abnormal curves have been corrected. It is easily understood that, since the shortest distance between two points is a straight line, a curved or bent septum forced into a straight line by dilatation of the nostril or by incision, has a tendency to reproduce the curvature within a few weeks after the operation. In such cases it is usually necessary to remove a portion of the septal cartilage, if permanence is to be given to the straight position obtained by the operation. This is sometimes done by excision of a portion of the septum by means of a nasal punch or a knife, thus leaving an opening between the two nares. The operation which I describe, and which is a resection of the cartilage beneath the mucous membrane, makes no opening between the two nares and yet gets rid of the surplus septal tissue.

The operation should be commenced by dilatation of the occluded nostril with the finger or a pair of dilating forceps; the mucous membrane covering the septum of the occluded side is then incised by means of a blunt tenotome. The incision should be a long curved one, with the convexity towards the floor of the nostril, and should be commenced as far back as is necessary to make a flap large enough to uncover the curved piece of cartilage. A flat, dull instrument is then slipped under the mucous membrane and used to separate this membrane from the triangular cartilage and vomer. A finger in the opposite nostril gives rigidity to the septum during the manipulations. After the large flap of mucous membrane has been elevated a blunt-pointed tenotome is thrust under the mucous membrane, which hangs down like a curtain, and is used to cut out an elliptical portion of the septal cartilage corresponding in size with the angle or curve in the deviated septum that the surgeon desires to remove. During this stage of the operation the little finger of the other hand in the opposite nostril is used to prevent perforation of the mucous membrane in the nostril opposite that of operation. A blunt instrument is then thrust through the incision in the cartilage and used to separate the portion of cartilage, which is to be taken out, from its mucous membrane on the side opposite the occluded nostril. The elliptical piece to be resected is then lifted out with forceps and the large flap of mucous membrane permitted to drop in place like a curtain. One or two sutures of catgut may then be put in the mucous membrane at the anterior portion of the wound in order to hold the flap in place.

The operation is readily performed, and

[1] Read before the Philadelphia County Medical Society, May 14, 1890.

seems to me a distinct improvement in nasal surgery. So far as I know it is novel.

My observations have led me to believe that a great many cases of crooked nose or occluded nares are not due to fracture or congenital deformity, but to interstitial growth of the septal cartilage. It is impossible to increase the area of a partition situated between fixed borders without causing the partition to assume a curve. The triangular cartilage cannot extend upwards, downwards or backwards, because of its margins in these directions being fixed, hence, when it increases in area by abnormal growth it assumes curves and distorts the anterior portion of the nose.

I have recently operated upon a case in which the crookedness of the nose was very marked, and had been increasing within the last few years. In this case it was quite evident that the deformity depended upon a double curve of the septal cartilage, which was apparently due to abnormal interstitial growth.

Submucous resection of the cartilage is, it seems to me, a good method for relieving many cases of nasal deformity. The removal of angular or curved portions of cartilage without cutting away the mucous tissue is an operation giving rise to no great hemorrhage, although, of course, the bleeding is free.

I show to-night an elliptical section of cartilage, the result of an operation done by this method. In this case, as the members will see, I cut out a portion of the bone as well as of the cartilage, and I subsequently removed another small piece of bone at the back part of the nares, by using a saw pushed under the mucous flap. The small portion of bone attached to the elliptical strip in the specimen was removed by the incisions made with the tenotome. The anterior portion of the bone of the septum is so thin that it is easily cut through with a tenotome.

The relief of nasal obstruction was immediate and very satisfactory in this case.

An Antipyrin Incompatible.—M. Tardy, a pharmacist, has observed that when antipyrin and carbolic acid are prescribed in the same mixture, an insoluble, oily liquid will separate and probably impair the properties of either or both of the constituents. The upper, or watery, layer appears to contain most of the antipyrin, and the lower oily stratum most of the carbolic acid, but both somewhat altered in odor and appearance.

TREATMENT OF PNEUMONIA WITH ERGOT.

BY J. KNOX HODGE, M. D.,

PRINCETON, ARK.

The controversy now going on in some of our best periodicals (notably the Medical and Surgical Reporter) as to the propriety or impropriety of using powerful arterial sedatives in the treatment of pneumonia, is really perplexing to the busy practitioner, who adopts the most modern and most highly endorsed plans of treatment in this disease; using, with high authority, such remedies as aconite, veratria, digitalis, etc., yet losing at best a considerable percentage of his cases.

In perusing Dr. Hiram Corson's second paper on pneumonia in the Reporter for March 29, I am favorably impressed, and heartily concur with him in his condemnation of this class of remedies, but cannot follow him further and endorse his practice of promiscuous "blood-letting" in this formidable disease; yet, did I not possess a remedy superior in my judgment to either, I should confess that his objections to the powerful sedatives are valid, and his theory of venesection plausible, and I should adopt the latter as the lesser evil.

In ergot and its preparations, we have a remedy that meets the indications in any stage of the disease, especially the first and second, and which in my hands has been eminently successful in combatting the same. It is a fact long since established that this article possesses the peculiar property of producing contractile action of the non-striated muscular fibres of any distended vessel or organ, for example, the impregnated uterus, enlarged spleen, myomatous tumors, etc. The various stages of pneumonia present somewhat analogous physical conditions. In the first stage the blood-vessels are engorged with blood and the air cells filled and distended with a sero-mucous effusion; in the second, the condition of affairs in not materially changed, except that a plastic extravasation has taken place, and the air cells are still further distended with a concrete and bloody lymph; whilst, in the third, the plastic secretion has been supplanted by a purulent fluid. Is it not at least reasonable, then, that ergot, which possesses this peculiar contractile power in just such conditions, would be strongly indicated in reducing the abnormally distended

blood-vessels and air cells to their normal caliber, and thus disgorging the diseased organ and terminating successfully a diseased condition, which otherwise so often proves fatal?

Now I would say to my brother practitioners, that this is not merely a theory, but has been put into practice by the writer, with the best and most satisfactory results, having previously for a period of several years resorted to the antiphlogistic treatment, both by blood-letting and by arterial sedatives with a much greater mortality. During the present season this disease has been unusually prevalent, appearing, too, in most cases, in an aggravated form; a great many of its subjects being previously debilitated by the ravages of epidemic influenza —yet not a single case under my treatment has proved fatal during a period of one year, since which time I adopted the foregoing theory and put it into practice. It is my custom when called in the first and second stages of pneumonia to prescribe the following:

℞ Ext. ergoti fluidi . . . . . ʒiv
Tinct. gelsemii
Vini antimonii āā . . . . . ʒii

M. Sig. Thirty drops every two hours, to be increased if necessary.

The object in using the mild and safest of all sedatives, gelsemium, is to adapt the heart's action to the sudden transition from a greatly distended to a much reduced and contracted caliber of the blood-vessels of the lungs, preventing too great frequency of pulsation, which would generate a high temperature, calling for antipyretics, which I rarely find necessary to use. The antimony exerts a special influence upon the skin, which I find a valuable adjunct in the treatment.

In a more advanced stage of the disease the foregoing prescription would be supplemented to meet the more prominent symptoms of the case. During the suppurative stage of the disease salol has proved of much value in my hands. I would admonish any one against doubting as to "whether a cure was ever effected in this stage of the disease." Should typhoid symptoms supervene, during the progress of the disease, the compound solution of iodine will prove most valuable.

Now the treatment of pneumonia as here given lacks but one thing to fully recommend it to the profession—it does *not* "furnish opportunities for *post-mortem* investigations."

INHALATION OF HEATED AIR.

BY JACOB R. LUDLOW, M. D.,
EASTON, PA.

Since the middle of June, 1889, I have been trying the hot-air treatment so highly extolled by Dr. Weigert, of Berlin. My experiments have not been exhaustive, nor as thorough as might have been desired, because I was never able to get patients to submit to sittings of two hours twice a day, as required by the Berlin practitioner. The best I could do was to get a half-hour twice a day, or about three-fourths of an hour once a day. In all, I have used it in six cases: three of phthisis of three or four years' standing, and three of what might be called incipient phthisis. The results, although not brilliant, were certainly not quite negative.

The inhalation of air heated to 280° F., raised the axillary temperature from one and one-half to two degrees. It can be used without harm or discomfort as high as 350° F. It produces a feeling of warmth in the lungs, chiefly of the diseased portions, rather agreeable than otherwise. It produces this feeling of warmth in the region of the stomach if there is coincident catarrh of that organ. It produces generally a feeling of heat over the whole body, rather uncomfortable, and sometimes followed by free sweating. It produces a huskiness of the voice which passes off entirely within an hour after using it. By continuous use the feeling of heat in the diseased lung, which is noticeable at first at a temperature of 212°, gradually becomes less, until 350° is easily borne. Two persons under treatment tell me they use it sometimes at 380° and 390° without discomfort; although I have generally advised keeping the heat at from 280° to 300°.

The three old cases were not cured; but they were not injured, and in some respects they seemed improved after using it three months. Two cases were subject to hemorrhages; but the hemorrhages were not oftener during its use than before. One patient developed a remarkable appetite after using it about two weeks, gaining strength, and was certainly better.

Of the incipient cases, two were suffering,

and had been suffering for some time, with cough and a marked dry, husky and stridulous voice. In both these cases, after about three months' use, once a day, the hoarseness and harshness of the voice disappeared, and the tone of voice became so much more pleasant as to be remarked by friends. One of these patients, after three months' treatment, went West and got married. The other came to my office about a month ago and reported herself better than she had been for years, with her cough gone, and, indeed, quite well; but she requested to keep the inhaler until warm weather, as she said that she found if she caught cold a few sittings would relieve her.

In the other case, the sixth, there was rhinitis with partial stenosis. I have used the hot air through the nose. It was noticeable that in one nostril the utmost heat that could be borne was 180°, in the other 200°. After a week 200° could be borne in both nostrils, and at the same time the air could be inhaled through the mouth at 350° easily, and the patient informed me that she had used it at 390° without discomfort.

The results are: a marked improvement in the general condition of the patient; an almost complete removal of the stenosis; a disappearance of the redness and puffiness of the nose, which has now a paler and more delicate look; and increased toleration of the hot air, which the patient can now use without inconvenience at 270° F., and which she informs me is followed by a free discharge from the nose, and by a subsequent feeling of marked relief and comfort. This patient informs me that her cough is nearly gone, her appetite good and that she considers herself quite well.

It must be understood that general medication was not suspended during the trial of heated air, either in this instance or in any of the others, so that the hot air is not the only factor to be considered. But my impressions are that it is not wanting in therapeutic value.

The last patient was examined by Dr. Curtin, of Philadelphia, who kindly communicated to me his views of her condition.

SACCHARIN HARMLESS. — The Supreme Sanitary Council of Vienna has recently published a report on saccharin, in which it is affirmed that no ill effect is produced on the human organism by that substance, and that it can be used as freely as ordinary groceries.

SOCIETY REPORTS.

AMERICAN MEDICAL ASSOCIATION.

Forty-first Annual Meeting, at Nashville, Tenn., May 20–23, 1890.

Third Day, May 22.

Hydrophobia.

DR. HAROLD N. MOYER, of Chicago, then read a paper entitled "Hydrophobia, a Clinical Study, with Statistics and Reports of Cases." The speaker objected to the word hydrophobia as misleading, and describing only a symptom and not peculiar to the disease under consideration. He preferred the term rabies. The author's conclusions are that there is a substantial identity between rabies, as seen in this country and Europe; that it is not a psychosis, and bears little or no relation to diseases of the mind.

DR. H. B. BAKER, of Lansing, Mich., read a paper on "Malaria, and the Causation of Periodic Fevers, showing their Dependence on Certain Meteorological Conditions." DR. GEORGE DOCK, of Galveston, Texas, read a paper on "Researches in the Etiology of Malaria and the Micro-organisms of Laveran."

In the Section of Obstetrics and Diseases of Women, DR. MARIE WERNER, of Philadelphia, read a paper upon the

Fistulous Escape of Ligatures after Abdominal Operations,

in which she advocated good drainage and detailed the dangers following abdominal section. Dr. Werner described two cases in which the stump ligatures were thrown off by fistulous tracts on account of leaving the drain too long time in place—eight days in one case, three weeks in the other. Statistics were read to prove that nearly every operator has had just this trouble.

A long discussion followed the reading of this paper.

Intestinal Obstruction.

In the Section of Surgery, DR. C. G. CARPENTER, of Stanford, Ky., read a paper on the necessity for early abdominal section in cases of intestinal obstruction.

DR. NICHOLAS SENN, of Milwaukee, advised immediate operation, not only *after*

diagnosis, but as a means of diagnosis. In obstruction due to paretic inflamed bowel he would restore the continuity of the intestinal canal by lateral apposition—since the increased vascularization of the gut walls will cause union even more rapidly than that which takes place in normal intestines. The condition of the gut is such that circular enterorrhaphy is absolutely unjustifiable.

Major Amputations.

The management of major amputations was then ably discussed by Dr. John A. Wyeth, of New York. His address opened with the statement that the prevention of hemorrhage is of chief importance in these operations, and after this comes the preservation of as much of the limb as possible. The next paper was read by Dr. H. O. Marcy, of Boston, upon "The Surgical Treatment of Biliary Obstruction." Several cases were carefully reported, and a *résumé* of the whole subject of the surgical management of this class of cases was given.

In the discussion of wounds of the abdomen, Dr. Senn said that he did not think that every perforative wound of the abdomen indicated laparotomy. The indication for laparotomy is hemorrhage, as shown by the classical symptoms.

Fourth Day, May 23.

The fourth day's session opened with the reading of Dr. A. L. Carroll's address on State Medicine, by title.

New Rules for the Association.

Dr. Brodie offered the following resolution, which was adopted:

Resolved, that at the next meeting of the American Medical Association, tickets for admission to the first two meetings shall be given each member upon the payment of his annual dues, the same to be shown at the door to a person appointed for the purpose.

Resolved, that the placing of all papers and periodicals in the seats for delegates or others, whether relating to the association or not be prohibited at the next meeting.

The following resolution by Dr. Hollister was adopted: Whereas, certain parties, without authority, are presuming to make use of this association for the furtherance of advertising interests; therefore,

Resolved, that at all future meetings of the association such publications be excluded from the places of meeting either of the general sessions or its sections.

Resolved, that in the future each Chairman of a committee of arrangements be directed to procure a copyright of the official programme to the end that the financial rights of the association may be protected by the due process of law. The following resolution, by Dr. Culbertson, was presented: Resolved, that the following by-law be added to the by-laws of the association: that the State and geographical district societies in affiliation at this time with this association having a membership of 100 or more, shall be recognized as branches of the American Medical Association.

Resolved, that all members of said society shall enjoy all the rights and privileges now accorded the delegates.

Resolved, that the said organizations be overtured through our Permanent Secretary to take such action as will enable them to concur in these resolutions.

This resolution was discussed and endorsed.

Dr. Love presented his resignation from the Board of Trustees of the Journal. President Moore was elected in his place.

The committee appointed to confer with the American Pharmaceutical Association recommended the following resolution, which was adopted:

Resolved, that the words Materia Medica be taken from the title of Section 1 and that a new section be formed to be entitled the Section of Materia Medica and Pharmacy, to have the same privileges as other sections of this association.

The following officers were elected for the new section: Dr. Frank Woodbury, of Philadelphia, Chairman; Dr. W. G. Ewing, of Nashville, Secretary.

Medical Exhibit at the World's Fair.

The following resolutions passed by the Illinois State Medical Society were read and approved:

Resolved, that at the World's Columbian Exposition to be held in Chicago in 1893, there should be such an exhibit as will represent the history, progress and present status of the medical and allied sciences, and that this society hereby requests the American Medical Association as the largest and most representative organization of medical men in this country to take the

initiative and inaugurate such measures as will secure a creditable medical exhibit.

Revision of Coroner's Laws.

The Committee on Coroners reported that they had examined the laws of the various States in regard to Coroners, and recommended the need of a revision of these laws. In most States the office is flagrantly neglected. It is too often considered a political position and incompetent men are allowed to fill it. They called attention to the fact that for some years the laws for Coroners in Massachusetts, Connecticut and a few other States had received the necessary revisions, and that the legal aspect of the office was not only properly provided for, but there was, in addition, a board of trained experts called Medical Examiners who looked after the more important medical and physiological features. They, therefore, recommended that the American Medical Association call the attention of the State Boards of Health to the necessity of a careful revision of the Coroner laws.

The following communication from the Tennessee State Druggist Association was then read:

Resolved, that a committee be appointed to lay before the American Medical Association the growing evil of prescribing secret and proprietary preparations by many members of the medical profession; that many of such preparations are frauds, the formulæ often stated on the label are misleading if not fictitious, and that all such preparations should be classed as secret, proprietary or patent medicines, and that the American Medical Association be petitioned to declare it against its code of ethics for any member of that body to prescribe any such preparation.

The President-elect, Dr. Briggs, was then introduced by the retiring President. The final motion to adjourn was then made.

Alcohol in British Hospitals.—From a very interesting report presented to the British Medical Temperance Association it appears that there is a very marked decrease in the amount of alcohol prescribed in 113 hospitals from which a report was received. Collectively the decrease amounts to nearly 50 per cent. as compared with a period twenty-five years ago. There is no doubt that, as a rule, alcohol is too freely and frequently given to hospital patients.

Periscope.

Succi, the Fasting Man.

At three o'clock in the afternoon of Saturday, April 26, the term of forty days which Signor Succi was to endure without eating any food came to its end, having begun at that hour of the day on March 17. The sequestered and canopied space in the Royal Aquarium at Westminster, prepared for his abode, has been daily visited by numbers of people, willing to pay an extra fee, and their curiosity has been gratified by seeing an Italian gentleman, of sallow complexion and evidently, though muscular, without an ounce of spare flesh, neatly dressed and seeming quite at his ease, sitting at a small table raised upon a platform, behind which is the bed where he sleeps at night. At a lower table sit two or three gentlemen supposed to look after the business, with whom may be associated some volunteer belonging to the medical profession—if not a qualified practitioner, it may be a student of the medical school of one of the London hospitals; but we are unable to state what official authority, from the recognized staff of any of those institutions, has made itself in any degree responsible for observing a case of such great scientific interest. The only professional gentleman who gives his name, so far, to authenticate the case is Mr. G. N. Robins, of 46 Marsham Street, M. R. C. S., London and L. R. C. P., Edinburgh, who signs a daily bulletin exhibited at the entrance, testifying the results of his examination, the accuracy of which there is no reason to doubt. For example, on Monday, April 21, the thirty-fifth day of this trial, it was certified, by the usual report of tests, that Signor Succi was "slightly weaker," that his pulse was 52, his respiration 19, his temperature 97.4, his weight 95 lb. 5 oz.; his muscular strength of hand-compression, by the dynamometer, equivalent to 47 kilogrammes; and his lung-power, by the spirometer, 1500 cubic centimètres. It was further stated that he had remained in bed all day on the Sunday, and in the night had slept, at intervals, about seven hours and a half; that he had drunk, in the day, ordinary water to the amount of 15½ oz. weight, besides 10 oz. of Kaiserbrunnen alkaline table-water; that an emetic of warm water had been administered, causing a return of 8½ oz.; and that an enema had been applied, at ten in the morning, the result of which was speci-

fied. We are told, by those who conduct the exhibition, that Signor Succi has eaten nothing, and has not taken, in any way, a particle of nutritious food, since March 17; and, though it is generally not easy to prove a negative, they may be prepared with evidence that would satisfy a jury of the truth of this assertion. In the meantime, some people will suspend their judgment; and the evidence, when fully set forth and authenticated, to the effect that Signor Succi cannot possibly have taken food, must be criticized by the ordinary rules of historical or judicial inquiry. Without anticipating the verdict of public opinion we present two illustrations of this remarkable affair, leaving our readers to think of it as they may. Giovanni Succi, who is thirty-seven years of age, is a native of Cesenatico, in the province of Forli, in the Romagna; he is son of a sailor, and was brought up to a sea-faring life, but had some college education, and became a banker's clerk in Rome; he afterwards traveled extensively in East Africa, was employed as commercial agent at Zanzibar, in 1880, by the Italian African Company, visited the Comoros Islands and Madagascar, the Portuguese dominions, Natal and the Cape. He invented an elixir, distilled from herbs, of which he is allowed to take twenty or thirty drops every day in his fasting trials, as it contains no nutritive matter, but is only an anodyne. The newspaper accounts of his repeated abstinences from food at Milan, Paris and Florence, during thirty days on each occasion, likewise at Barcelona, Madrid, Lisbon, Rouen and Brussels, since 1886, have gained celebrity; and the Academy of Florence awarded him a diploma of scientific merit. If his pretensions should be endorsed with equal authority in London, after the investigation and discussion that ought to follow this forty days' exhibition at the Westminster Aquarium, Signor Succi's fame will have been secured all over Western Europe. There are no signs of his being likely to kill himself by these experiments. The close confinement, day and night, to a gas-lighted, ill-ventilated apartment in the Royal Aquarium might have been expected to injure his health; but we do not hear that it is so. He has lost weight 30 lb. 14 oz. and three-quarters of an inch height. Signor Succi is a smoker, and is permitted to solace himself with a pipe or cigar whenever he pleases, but does not smoke so much as he used to do. He talks little, but reads the newspapers, and writes autographs for sale with copies of his portrait. An attendant showman discourses to the crowd of visitors. The managing director of the Aquarium says he cannot, if he would, force Signor Succi to take food. We feel sure that Signor Succi will never die of starvation, however long may be the periods of his fasting exhibitions in future: he knows very well, all the time, what he is doing to himself.—*Illustrated News of the World*, May 10, 1890.

Adulteration of Food.

In his annual address, delivered Jan. 23, 1890, before the Chemical Society of Washington, the retiring president, Mr. Edgar Richards, said that, from want of reliable information in regard to the materials employed in most new food products, there is a general feeling of uncertainty and insecurity on the subject. People, as a rule, imagine that any substance used as an adulterant of, or a substitute for, a food product is to be avoided as itself being injurious to health; and when they hear that a certain food is adulterated, or is a food substitute, there is immediately a prejudice excited against the article, which it takes time and familiarity to allay. A moment's reflection ought to show that it would be directly contrary to the food manufacturer's interest to add to, or substitute anything for, a food product which would cause injurious symptoms, as in that case his means of gain would be cut off by the refusal of consumers to buy his product. It is true that the unscrupulous manufacturer or dealer does not hesitate to cheat his customer in the interest of his own pecuniary profit and gain, but he does not want to poison him. Where, through carelessness or ignorance, injurious substances, such as the arsenic, copper, aniline, and other metallic and organic poisonous salts sometimes used for artificial colors, are added to foods, their presence is promptly revealed by the dangerous symptoms which they call forth in the consumer. About a year ago some Philadelphia bakers added chromate of lead to color their cakes, and caused the death of several persons, and serious illness in nearly every one who ate any of these products.

The great majority of substances used for food adulterants or substitutes consist of cheap and harmless substances, which are not injurious to health, as the following list of those most commonly met with in the

principal food products will show. This list has been compiled from the reports of the State boards of health, the returns of the British Inland Revenue Department, the reports of the British Local Government Board, and those of the Paris Municipal Laboratory.

Food Products and their Chief Adulterants.

FOOD PRODUCT.	ADULTERANTS.
Milk	Water, removal of cream, addition of oleo-oil or lard to skimmed milk.
Butter	Water, salt, foreign fats, artificial coloring-matter.
Cheese	Lard, oleo-oil, cottonseed-oil.
Olive-oil	Cottonseed and other vegetable oils.
Beer	Artificial glucose, malt and hop substitutes, sodium bicarbonate, salt, antiseptics.
Syrup	Artificial glucose.
Honey	Artificial glucose, cane sugar.
Confectionery	Artificial glucose, starch, artificial essences, poisonous pigments, terra alba, gypsum.
Wines, liquors	Water, spirits, artificial coloring-matter, fictitious imitations, aromatic ethers, burnt sugar, antiseptics.
Vinegar	Water, other mineral or organic acid.
Flour, bread	Other meals, alum.
Baker's chemicals	Starch, alum.
Spices	Flour, starches of various kinds, turmeric.
Cocoa and chocolate	Sugar, starch, flour.
Coffee	Chicory, peas, beans, rye, corn, wheat, coloring-matter.
Tea	Exhausted tea-leaves, foreign leaves, tannin, indigo, Prussian blue, turmeric, gypsum, soap-stone, sand.
Canned goods	Metallic poisons.
Pickles	Salts of copper.

The use of flours and starches of various kinds—wheat, corn, rye, peas, beans, etc.—as food adulterants cannot be considered injurious to health. However much the public may be cheated in the purchase of such adulterated articles of food, as ground spices, coffee, etc., they are not poisoned by their consumption. It is a question how much a purchaser is himself to blame, in his endeavor to secure a "bargain," when he demands so great a quantity of any given material at less than it can be purchased at wholesale in the market, that he compels the unscrupulous manufacturer to make a compound which has never more and generally less than the proportion of the genuine material represented by the price asked.

Many articles of food spoil in transportation; and, under the plea of preventing further fermentation, resort is had to antiseptics, such as salicylic acid, sulphite of soda, borax, etc. These deserve mention as being additions to foods of a class of substances used to cloak carelessness in manufacture and otherwise, and producing in many cases deleterious effects on the human economy. In France and Germany the use of such antiseptics as salicylic acid in food products is prohibited, although in the latter country such addition is tolerated when the food product is exported to countries where such use is not prohibited.—*Science*, Feb. 7, 1890.

Hunterian Chancre of the Face.

On the invitation of Dr. White, Mr. Frederick Treves, of London, delivered a clinical lecture to the Ward Class at the University Hospital, in which he described a case of Hunterian chancre of the face as follows:

"This patient is exceedingly interesting from several points of view, and particularly as showing how little reliance should be placed in the history of disorders as ordinarily given. She comes to us to-day with two large ulcers upon the surface of the left cheek—one, the size of an infant's palm, placed immediately in front of the ear; the other, not larger than half-a-dollar, separated from the larger granulating surface by half an inch of apparently healthy skin. We are told that these ulcers began five weeks ago as slight pimples, and have grown steadily worse in spite of treatment. On examination it is found that they have densely indurated and sharply circumscribed bases; that the secretion from them is comparatively slight; that the chain of lymphatic glands running down the neck is enlarged, each gland being felt as a hard, round globule. On further examination we find an efflorescence covering the greater portion of the body. This eruption presents the following characteristic appearance: It is rounded in form. It is unattended by itching. It is coppery in color. It is symmetrically placed, and it is polymorphous, that is, while in one place we have maculæ, in another papules are seen, or the eruption may still take other forms.

"With clinical symptoms such as these, your diagnosis is absolutely certain. Whatever be the social position of your patient, whatever be the history given you, you have here the characteristic features of the Hunterian chancre, with the early secondary eruption just beginning. The poultice which this patient has applied to her ulcers should be at once replaced by some form of mercurial dressing. She should be placed upon small doses of mercury internally, and under this treatment we can promise a speedy cure. With such a lesion as this you would of course expect much deformity, and in answer to the patient's question upon this point, you would naturally say 'Yes; there will probably be a considerable scar following the cure of this lesion.' As a matter of fact, however, in two or three years you will scarcely be able to perceive the seat of these large ulcers. I have seen cases more marked than this where, after the duration of some time, a casual observer would fail to notice that there had been any lesion. The character of the chancre is influenced greatly by its position, and the appearance of this one is quite typical of those found upon the face."—*University Medical Magazine*, Feb., 1890.

Successful Removal of a Cancerous Tumor from the Pancreas.

Professor G. Ruggi, of Bologna, has recently reported a case in which he successfully removed a cancerous growth from the pancreas. The patient was a woman, aged 50, who had suffered for some time from swelling of the abdomen, which caused great discomfort and occasionally severe pain. Though still well nourished, she had lost flesh considerably; the digestive functions were much disordered, but all the other organs seemed to be perfectly healthy. The patient suffered from profound mental depression, which she said was worse than her bodily sufferings. On examination the abdomen was found to be uniformly distended by fluid in the peritoneum, and two tumors could be felt, one above the other, with a distinct line of demarcation between them. The lower one was continuous with the body of the uterus, and was judged to be a fibro-myoma. The upper mass occupied the left colic and hypochondriac regions, and extended in front towards the umbilicus. Its posterior extremity corresponded to a prolongation of the mid-axillary line, and the anterior to a prolongation of the parasternal line. The tumor measured ten inches in its long, and five inches in its short, diameter. If the patient lay down with her shoulders lower than her pelvis the tumor disappeared under the arch of the ribs, returning to its natural position when she sat up. Vaginal examination, whilst confirming the diagnosis with respect to the lower tumor, threw no light on the origin or relations of the upper one. The spleen, kidneys and liver were normal to palpation. A provisional diagnosis of retroperitoneal adeno-sarcoma was made, and laparotomy was performed on September 4, 1889. The patient having been placed on her right side the abdomen was opened by a lateral transverse incision just under the left costal arch. In attempting to separate the tumor from the peritoneum, to which it was adherent in front, the peritoneal cavity was opened, and a quantity of yellowish fluid escaped. The mass was then drawn through the hole in the peritoneal sac, bringing with it the omentum and a loop of the small intestine surrounding the lower and inner end of the tumor. The latter was soft, like brain substance, and broke down under the fingers, but the operator was able by degrees to pick it off the intestine to which it was attached, a catgut ligature being applied here and there. The adhesions to the omentum were firmer, and that structure had to be divided into bundles, which were tied separately and cut through. The tumor when brought away was a shapeless mass of pulp, bearing no resemblance to the normal pancreas. The peritoneal cavity was carefully cleansed, and drainage-tubes placed in the posterior part of the wound. The front part healed by first intention, and the patient made an excellent recovery, being discharged cured on October 26. Her appetite was excellent, and the deep depression from which she had suffered before the operation had entirely disappeared. Recent accounts state that she is still in perfect health. The fragments of the growth removed weighed twenty ounces; microscopic examination proved it to be a glandular cancer. Professor Ruggi thinks that little or none of the affected organ was left behind; the opening into the duodenum was certainly destroyed. The patient's digestion, however, is perfect, although no particular precautions have been observed as to diet. —*British Medical Journal*, March 8, 1890.

Orthrine—a New Antipyretic.

The *American Druggist*, April, 1890, quoting from the *Chemist and Druggist*, says:

Under this name, Prof. Kobert recommends as an antipyretic a new derivative of phenylhydrazin, which has been obtained by the combination of hydrazin with paraoxybenzoic acid. This new body, orthohydrazin-paraoxybenzoate, is very unstable, but unites with hydrochloric acid, forming the hydrochlorate of orthrine, which is stable. Clinical experiments made with the new antipyretic by Prof. Unverricht show that, in 30 to 50 c.c. doses, orthrine acts in typhoid fever, pneumonia and articular rheumatism generally with great energy; but it is uncertain, and its advantages are slight compared with its disadvantages, amongst which are profuse perspiration, collapse and symptoms of intoxication. Michaelis has recently mentioned two other hydrazin derivatives which possess antipyretic properties; these are acetylethylenephenylhydrazin,

$$(C_6H_5)_2N_2.C_2H_4.N_2.2H(CO.CH_3),$$

and ethylenephenylhydrazin succinic acid,

$$(C_6H_5)_2—N_2—N_2—2H(CO.C_2H_4.COOH).$$

These two substances are yet on clinical trial, and it is to be hoped that they will have shorter names if they are to go down to posterity.

Simple Remedy for Thrush and Sordes.

A very simple and efficacious remedy for thrush and sordes was suggested by Mr. W. Theophilus Ord, of Bournemouth, England, in the *Lancet* last year. He says the following lotion, applied frequently with a feather or brush to the white patches, kills the oïdium albicans more quickly than any other he knows, and removes the patches after a few applications, leaving healthy mucous membrane. It consists of equal parts of black-wash and glycerine mixed. The quantity used is so small as to be quite harmless. Another condition in which he has found the same lotion valuable is that of sordes on the teeth, lips and tongue in many cases of enteric fever. It cleans these parts as if by magic, and renders that unpleasant process known as "scraping the tongue" quite unnecessary. It may also with advantage be painted over the fauces in unhealthy conditions of the throat common in typhoid. He tried it in one case of catarrhal stomatitis, but it had no effect, whereas chlorate of potash effected an immediate cure. Also in the sordes of advanced phthisis it seemed to be of no use. Part of the beneficial influence of the application is, no doubt, attributable to the glycerine.

Boroglycerine Cream.

The following formula for boroglycerine cream appeared in the *Chemist and Druggist*, April 26, 1890: Dissolve 15 grains of boric acid in 4 fluid drachms of glycerine, using a little heat to aid solution. Set aside to cool, and meanwhile melt together 80 grains of anhydrous lanoline and 2 oz. of vaseline, coloring the fatty mixture with a $\frac{1}{10}$ grain of alcanin. Incorporate the boroglycerine and perfume with 1 drop of otto of rose and 1 drop of bergamot. This preparation is, according to Dieterich, who has devised the formula, equally suitable for the hands, lips, etc.

Hot Fomentations in Atrophy of the Optic Nerve.

A case of atrophy of the centre of the optic nerve is reported by Dr. Segall in the *Lancet*, May 3, 1890, in which, after mercurial inunctions and strychnine injections had been employed with only very temporary benefit, the application of hot fomentations two or three times a day to the occiput for fifteen minutes at a time produced a very marked improvement, the amount of vision being doubled. A still more marked improvement was noted when fomentations were applied simultaneously over the closed eyes. Unfortunately, however, the good effect of the fomentations was, like that of the more usual forms of treatment, of but very limited duration.

Menthol in the Vomiting of Pregnancy.

L. Weiss, in the *Therapeutische Monatshefte*, quoted in the *National Druggist*, May, 1890, says the following has proved very efficacious in his hands:

℞ Menthol . . . . . ℥i
Alcohol . . . . . f℥iiss
Simple syrup, q. s. ad . . . . . f℥vii

Mix. Dose: A teaspoonful every hour until relieved.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

OBJECTIONABLE CENSUS QUESTIONS.

Dr. Benjamin Lee, Secretary of the Pennsylvania State Board of Health, has sent to the editorial office of the MEDICAL AND SURGICAL REPORTER a circular addressed to physicians in Pennsylvania, in which he urges them to answer what we termed "Objectionable Census Questions," in an Editorial in the issue of June 7. Dr. Lee says: "An opportunity is afforded in connection with the taking of the census by the United States Government, of obtaining statistical information which cannot fail to be of extreme value to the State, as regards the physically defective classes which compose a portion of its population. The State Board of Health, to which has been confided the duty of superintending the collection of vital statistics in this Commonwealth, is desirous that these returns should be as full as possible."

Dr. Lee goes on to explain that he has written to the Census Office and got an assurance that the returns of physicians will not be made public, and he urges physicians to answer.

When speaking on the subject, on June 7, we gave what we regard as a sufficient reason why physicians should not answer the objectionable census questions; but we will add something to what was then said.

We do not share the generous opinion of Dr. Lee that it is safe to confide to the census enumerators or clerks the secrets of those who have trusted to our honor as medical men. On the contrary, we think no physician is warranted in committing these confidences to such men as some are who do the census work, even on the assurance of the authorities that they will not tell. There has been a good deal said about the heavy fine to be imposed on an enumerator who reveals what is told him. But, is there any man of average intelligence who would like to have an enumerator know that he has syphilis, for example, and take the chance of having him detected in revealing the fact or punished by the great United States Government in case he should tell of it to another, now or after the lapse of a few months? Supposing these secrets are sent direct to Washington and burned up, after being tabulated, as we are told they will be: what right has any physician to send to a lot of clerks gathered from different parts of the country a set of papers in which—if they are to have any value—they must carefully study the names and addresses of those reported as defective or diseased? Would any man feel like trusting his own secret to the chance that it would not be carefully remembered, and perhaps some day divulged by a clerk who came from his own neighborhood? And, is any medical man justified in making such a revelation of another's secret possible? By no means; and let no medical man do it! On this ground alone,

we again urge the readers of the REPORTER to let the census men have no share in their professional secrets.

But, besides this, we have no notion that the census statistics of physical defects and diseases will have any value at all as statistics. Those who know the way in which census statistics are collected, and who have any knowledge of human nature, will know that on this head they will be somewhat worse than useless, because there will perhaps be a few persons who think they have some value. If they are utterly discredited they cannot do harm; but if they are trusted at all, they surely will.

It would have been much better if Dr. Billings—who, we are informed in a circular from Washington, dated June 4, is "now absent"—had never prompted the introduction of such foolish and impossible questions, or if the census officers who are still in the country were to back squarely down about them, and acknowledge the mistake that has been made.

Certain we are that nothing can be gained by pushing them, and we hope that the attitude of the medical profession on this occasion will make it impossible for another census to be made the occasion of such a blunder.

PHYSICIANS AND INTEMPERANCE.

Not long ago the Philadelphia daily papers recorded at considerable length the circumstances connected with the death of two comparatively young men, who fell victims to the excessive use of alcoholic stimulants. One of these was a business man of fine culture, occupying a responsible position, and of entire financial integrity; the other was a medical man of considerable ability, of reasonable industry, and who had had every opportunity of becoming successful as a practitioner and as a writer. As is customary in such cases, every effort was made to lessen the painfulness of the circumstances to the families of those who died. This is an indication of kindness of heart which does credit to the managers of the newspapers, but we doubt if it is in the line of wisdom; for it appears as if, in this day, too much were done to remove the burden of responsibility for one's actions from the individual who does wrong to those who surround him, or to the circumstances in which he is placed, and that there is entirely too much fear and unwillingness to speak plainly in regard to wrong-doing, in order to warn those who have not already committed themselves to unfortunate ways and to maintain a strict standard of uprightness. For this reason we refer to these deaths, and especially to the one of the physician mentioned, who began to be a slave to alcohol and to opium several years ago, and whose downfall appears to have been a gradual progression. He came to be more and more intemperate, until, in consequence of shameful conduct on his part while grossly intoxicated, his career terminated in a helpless fall down a flight of stairs, a fracture of the skull, a hospital bed, and a Coroner's inquest.

The plain statement of one case, like this, ought to exert an influence upon medical men who are in any danger of being beguiled to the habitual use of any alcoholic or narcotic stimulant. None know so well as we do the insidious approaches by which these enemies of mankind obtain control over the most promising and sometimes the apparently most virtuous. And none should so strongly combat the practice, into which physicians themselves sometimes fall, of habitually using these things for the relief of conditions which a little patience and endurance would enable them to surmount without artificial aid. And above all, physicians ought to understand that they, least of all, have a right to expect that the cover of euphemism should be thrown over their weakness and their wrong-doing, if, with all the light that they have on this subject, with all the examples that are continually coming under their notice, they themselves become addicted to habitual excesses.

It is painful to have to record such cir-

cumstances as we have referred to above, but if doing so shall be of any service to any member of the medical profession, young or old, the occasion will not have been misused.

TREATMENT OF OBSTINATE CONSTIPATION BY DILATATION OF THE ANUS.

All physicians recognize the importance of keeping the bowels, the great sewer of the body, in an active condition. The moment they become sluggish, the fecal matter which should be expelled promptly begins to be reabsorbed and gives rise to various local and reflex irritations. Few, however, have thought of employing forcible dilatation of the anus in even the most obstinate and rebellious cases of constipation. The measure appears at first sight unnecessarily heroic; but, as it is urged by Monod, a well-known French surgeon, it cannot be passed by with a mere shrug of the shoulders.

In the *Annales de Thérapeutique Medico-Chirurgicales*, March, 1890, Monod relates in detail the history of two cases in which this operation was performed with marked success. In the first case, a woman forty-five years old had suffered for some years with digestive troubles, which she thought were due to a tumor of the bowel. Digestion was disturbed by swelling of the belly and eructations, with a feeling of weight in the lower part of the abdomen, and with constipation alternating with diarrhœa. On examination of the rectum, Monod found that the tumor was an enormous lump of hardened feces, the presence of which had not been suspected because there had been no sign of obstruction of the bowels recognizable by the patient, as the fecal matter, rendered fluid by repeated purgatives, slipped over the hard mass. After dilating the anus instrumentally, the mass referred to was broken up with the fingers and was removed, together with a vast number of scybala. A laxative given in from twenty-four to forty-eight hours completed the clearing out. As six years have elapsed since the operation, and the patient has had no return of her troubles, there is some ground for regarding it as curative. Of course, however, careful instructions were given regarding the regulation of the diet.

In the second case, a woman, fifty years of age, suffered with habitual constipation and various digestive troubles brought about by it. The use of repeated injections and laxatives, or, in their absence, the passage through the rectum of hard fecal matters had induced a condition of habitual irritability of the anus, never, however, amounting to the cutting pain of fissure. Monod dilated the anus; and the patient's distressing symptoms disappeared and gradually she was able to do without laxatives.

Monod says these are not the only cases of the kind he could cite. They are sufficient, however, to illustrate the fact that some cases of constipation depend upon a local removable lesion of the lower part of the rectum and of the margin of the anus, which can be remedied by dilatation of the anus. This treatment must necessarily have a very limited range of applicability, but it certainly appears worthy of consideration in the management of cases in which constipation is the result of habitual spasm of the sphincter ani, set up by hemorrhoids, fissure, eczema or—as apparently in the first case—by an impassable ball of hardened feces.

—The Philadelphia Board of Health has adopted a series of new rules, relative to the interment of bodies, registration of deaths, etc., to go into effect July 1. Under the new rules no interment will be allowed without a permit from the Board, instead of permitting the certificate of death to serve as a permit for interments, as at present. A new rule is provided extending the office hours of the Registration Office. Another rule requires that all coffins, etc., used to carry a body to any crematory must be burned at once at the same place.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

ZUR RADICAL OPERATION DER UNTER-LEIBSBRUCH, von Dr. Friedrich Walter, Hamburg. SAMMLUNG KLINISCHER VORTRAGE. No. 360.

RADICAL OPERATION FOR ABDOMINAL HERNIA. By Dr. Friedrich Walter, Hamburg. 8vo, pp. 59. Leipzig: Breithopf & Härtel. April 21, 1890. Price, 75 pfennigs.

Dr. Walter tabulates 165 cases of hernia under the care of Schede at the general hospital at Hamburg, between the years 1880 and 1888, in which radical operations were performed. There were 51 cases of incarcerated and 40 of not incarcerated inguinal hernia in 79 males and 9 females; 64 cases of incarcerated and 10 of not incarcerated femoral hernia in 70 females and 4 males, of all of which 95 were right-sided and 67 left-sided. Of these 43 were completely cured. In 15 the results were imperfect or recurrences followed. A case was considered cured if the hernia had not returned at the end of a year. In 95 high ligation of the sac was performed, with extirpation and with closure of the ring; in 17, of which 15 were cases of femoral hernia, ligation of the neck was done and the sac extirpated; in 15 the ring was closed by suture, probably with ligation of the neck of the sac; in 3 the inguinal canal was exposed by division; in 11 the method was otherwise modified; thus, in 2 cases the sac was used to cover the bed of the hernia, and in 1 it was pushed beneath the peritoneum and the ring was closed. In 24 cases the method was not indicated.

In 53 cases the omentum was tied with catgut and removed, and the stump was permitted to retract. As a rule the sac was completely removed. Partial extirpation was done only in cases of congenital inguinal hernia. Care was taken to avoid injuring the testicle and epididymis. In one case the vas deferens was accidentally severed and then sutured.

In most cases narrowing of the hernial ring was attempted. It was omitted in 15 of 74 cases of femoral hernia and in 2 of 91 cases of inguinal hernia. Minor complications arose in about 62 per cent. of the cases, grave complications in 7 cases, of which 4 terminated fatally.

DER GEWOHNLICHE UND UNGEWOHNLICHE WANDERUNGS-MECHANISMUS WACHSENDER EIERSTOCKSGESCHWULSTE, von Dr. H. W. Freund, erstem Assistent der Frauenklinik zu Strassburg. SAMMLUNG KLINISCHER VORTRAGE. Nos. 361 and 362.

THE USUAL AND UNUSUAL MECHANISM OF THE RELATIONS OF GROWING OVARIAN TUMORS. By Dr. H. W. Freund, first assistant at the gynecological clinic at Strassburg. 8vo, pp. 72. Leipzig: Breitkopf & Härtel. April 21, 1890. Price, one mark and a half.

In quite an elaborate paper, including a table of 200 cases of ovarian tumors, Freund explains the mechanism of the relations of such tumors at different periods of their development. He makes an analogy between the growth and development of ovarian tumors and the growth and development of the pregnant uterus. Both result from a mechanism governed by fixed laws affecting the tumor and adjacent organs. The author distinguishes a normal and an abnormal mechanism and recognizes two stages. In the first stage of the normal mechanism the tumor grows in the direction of least resistance. This is towards Douglas's cul de sac. It pushes the uterus forward and somewhat laterally, and produces pressure upon the bladder and rectum. In the progress of its development it meets resistance at the floor of the pelvis. It now must needs ascend. This is the second stage. The tumor escapes at the superior strait, falls forward and lies in front of the uterus, at the same time rotating. It presses upon the middle of the fundus of the bladder, while the abdominal viscera are pushed upwards and backwards. The conditions favoring the normal mechanism are mobility of the tumor and of the uterus, ample room in the abdominal cavity and relaxation of the anterior abdominal wall. Any change in these conditions must modify the normal mechanism. So when the tumor is intra-ligamentous it pushes the uterus upwards and laterally, compresses the bladder and mayhap the ureters. If the tumor have early formed adhesions with the pelvic peritoneum, it can grow, but not wander; it lies behind the uterus, which it usually elevates. If the uterus is fixed in the pelvis, or if its mobility be impaired by unusual size or weight, such as may be induced by pregnancy or by neoplasms, the normal mechanism is altered. Lastly, rigidity of the abdominal walls may offer such resistance that the tumor fails to attain its normal relation to the uterus.

SAUNDER'S QUESTION COMPENDS. Essentials of Forensic Medicine, Toxicology and Hygiene. By C. E. Armand Semple, M. R. C. P. Lond., etc., Member of the Court of Examiners and Late Senior Examiner in Arts at Apothecaries' Hall, etc. With one hundred and thirty illustrations. Small 8vo, pp. xvi, 196. Philadelphia: W. B. Saunders, 1890. Price, $1.00.

The author has endeavored, in this little book, to condense the contents of such well-known text-books as those of Tidy, Woodman, Guy, Taylor and Caspar into the small space of a compend. He declares that it is not intended to exclude the use of the elaborate treatises, but merely to serve as an introduction to them and as a convenient way of refreshing the student's memory just before his examination. As the author makes no personal claim except for the form of the book, one is debarred from such criticism as would be in place concerning a more pretentious work.

In looking over the pages we notice some queer-looking spermatozoa figured on page 21. The author states, regarding the relative length of the head and tail, that the latter "is generally five or six times the length of the head;" it would be correct, according to Ultzmann, to say ten times the length of the head. It is objectionable, also, as tending to perpetuate a long-exploded notion, to speak of spermatozoa as "animalcules."

There is less need on the part of a student for a compend on this subject in the United States than in Great Britain, but those who desire a brief synopsis of the subjects mentioned will find it in Mr. Semple's book.

THE STUDENT'S SURGERY. A multum in parvo. By Frederick James Gant, F. R. C. S., Senior Surgeon to the Royal Free Hospital. 8vo, pp. xxxv, 817. Philadelphia: Lea Brothers & Co., 1890. Price, $3.75.

The present volume is a condensation of Gant's well-known work on the *Science and Practice of Surgery*. The chapters in the latter book on the

eye, ear, teeth, skin, female genital organs and orthopædics, which were contributed by special authorities, have been omitted, but the same order of arrangement in other respects has been followed.

The first part of the book is very properly devoted to General Pathology and Surgery, under which are included diseases of nutrition, diseases of the blood, diseases of contagious origin, and diseases of the nervous system. The second part of the book, on Special Pathology and Surgery, is taken up with injuries and diseases of textures, and injuries and diseases of organs and regions. Under the heading of Injuries and Diseases of Textures, in addition to skin, nerve, tendon, muscle and bone, etc., the author includes lymphatics and glands, veins, arteries, bursæ and joints. The special regions treated of are the neck, thorax and abdomen. The systematic arrangement adopted and the minute subdivision of the subjects in the table of contents (which covers thirty-four pages), make the absence of an alphabetical index a less serious fault than it would be otherwise.

The book is an excellent guide for students, in spite of the fact that some of the methods of treatment which the author advocates have now been superseded by better. The publishers have maintained their reputation by presenting it in handsome style.

Literary Notes.

—Emperor William has summoned a conference of eminent scholars to discuss the subject of a fixed uniform German orthography. The conference will be held in Berlin. Austria and Switzerland have been asked to send delegates.

—During the past two years from eight thousand five hundred to nine thousand manuscripts were annually submitted to *The Century Magazine* for publication. This is an increase over previous years, and does not include the hundreds, perhaps thousands, of propositions submitted with regard to articles. As there has been an increase in the number of periodicals published in America of late years, and as the newspapers are publishing more contributions than ever by writers not on the regular staff, it is evident that there has been an increase in literary activity at least in proportion to the increase in population.

—Some time ago we called attention to what we considered a fault in *Harper's Young People*, namely, the publication of a class of articles which might tend to injuriously affect children's nerves. In justice, we must now however say that the style of stories to which we took exception no longer find their way into *Harper's Young People*. The publication is instructive, interesting and innocent, and contains nothing that could harm any child's mind or nerves.

—The J. B. Lippincott Company announces in press an important work on *Regional Anatomy in its Relation to Medicine and Surgery*, by George McClellan, M. D., Lecturer on Descriptive and Regional Anatomy at the Pennsylvania School of Anatomy. The work will contain about 100 full-page illustrations reproduced from photographs of his own dissections, taken by the author and colored by him after nature. It will be in two volumes of 250 pages each, large quarto size. The object of the work is to convey a practical knowledge of regional anatomy of the entire body. The text to embrace, besides a clear description of the part in systematic order, the most recent and reliable information regarding anatomy, in its medical and surgical relations. The illustrations are intended to verify the text and to bring before the reader the parts under consideration in as realistic a manner as possible. The first volume will be ready for publication about December 1; and the second volume is expected to appear shortly thereafter. The work will be sold by subscription only.

Correspondence.

Peroxide of Hydrogen.

To the Editor.

Sir: The very practical character of the paper on peroxide of hydrogen by Dr. Noble in the issue of the Reporter of May 10, prompts me to remind its readers that this preparation deserves more than a passing notice. Dr. Noble remarks that the use of this remedy has been limited and that "the opinion expressed by many concerning its value has been uncertain, or certainly not laudatory." While it is true that a number of practitioners who have used the remedy is comparatively limited, the conclusion is scarcely warranted that its applications are limited, even if the expressed opinion has been somewhat uncertain. The reason for medical men being cautious regarding their views as to the value of peroxide of hydrogen arises from the fact that its employment amongst the laity has been conducted under the management of what are termed "quacks," or doctors who advertise, and as doubtless many of these persons have taken it under the expectation that it would cure maladies which are manifestly incurable, the doctor was apparently warranted in saying that it could not possibly be a cure-all, as some of the patients died.

For the purpose of bringing the matter more forcibly to the attention of the readers, permit me to quote from my work upon *Materia Medica*, which was reviewed in the columns of the Reporter March 15, 1890: "As compared with other antiseptics, it is claimed that the dioxide is forty per cent. more potent than mercuric bichloride, twenty times as powerful as salicylic acid and sixty times the activity of carbolic acid. . . . The topical uses of this remedy will include the local use by means of the spray or otherwise, in all such morbid conditions as gangrene, boils and carbuncles, indolent ulcers and carcinoma; also it may be used locally in venereal diseases. Shelly (*Practitioner*,

London, 1884), speaking of the local use of the dioxide, says, 'It is interesting to watch the action when a few drops of the proper solution are brought in direct contact with pus corpuscles.' A brisk effervescence at once commences and continues until all the pus is destroyed, and upon the basis he has suggested that it might be used for the detection of pus in the urine. Such qualities would naturally commend it to the attention of the gynecologist, the ophthalmologist and laryngologist." (This will serve to account for the peculiar experience which was noted by Dr. Noble when the solution was used for the disinfection and irrigation of the wound, when the patient experienced a sensation as if a soda-fountain was inside her.)

"In gynecological practice, a vaginal tampon may be prepared of absorbent cotton and introduced into a gelatin capsule along with the solution of the dioxide and a little glycerine, with the best results. . . . The above-described tampon may be used to good advantage by simply saturating the cotton with the ordinary fifteen-volume solution; but in introducing the tampon the necessary pressure will have a tendency to remove the greater part of the preparation, while by the use of the capsule, which will readily dissolve, the solution can be placed in the desired position."

The foregoing extracts are made simply for the purpose of emphasizing the article to which I have referred, and may be the means of attracting the attention of others whose opinions are still uncertain.

Yours truly,

JOHN AULDE, M. D.

1910 Arch street,
Philadelphia.

NOTES AND COMMENTS.

Quantitative Determination of Sugar in the Urine.

Dr. Charles W. Purdy, of Chicago, writes as follows in the *New York Medical Journal*, March 8, 1890, on quantitative testing for sugar in the urine:

I am sure it will be generally admitted that the methods of quantitative testing for sugar in the urine which have heretofore been in vogue require remodeling in order to meet the practical requirements of those engaged in active practice. Most, if indeed not all, the tests brought forward thus far are either complicated and time-consuming, unstable, or inaccurate, and therefore very far from perfect for practical purposes. Thus the fermentation test requires twenty-four hours' time to determine the quantity of sugar present; and with all possible care and precaution the results are by no means accurate.

Fehling's solution—the one perhaps most generally depended upon — is notoriously unstable, and consequently requires to be freshly prepared in order to be trustworthy. But, even when freshly prepared, Fehling's solution has been by no means satisfactory in my hands. The precipitation of yellow suboxide of copper renders the solution, when testing, so turbid that it is impossible to determine the precise point when the blue color is all discharged. The method advised to overcome this difficulty, by adding the urine little by little and then waiting for the precipitated suboxide to settle, consumes a great deal of time, and, moreover, it only in part remedies the defect referred to.

Dr. Pavy suggested the addition of ammonia, which holds the suboxide in solution, and this very much improves the working of the test. Unfortunately, however, Dr. Pavy's solution is even more unstable than Fehling's, and it is only possible to use it a few times before it becomes useless.

The chief difficulty with both Fehling's and Pavy's test solutions is the fact that the tartaric salt which they contain is very unstable, and cannot be put up in permanent form with strongly alkaline solutions of cupric sulphate. Now, the chemical principles upon which these tests are founded demand that some organic product should be present in the alkaline solution of copper, in order to prevent precipitation of the blue protoxide of the latter which would otherwise occur; and the tartaric salt usually employed for this purpose renders this solution unstable.

Acting in part upon the suggestion first made, I believe, by Schmiedeberg, that the substitution of pure mannite or the potassic or sodiac tartrate renders the copper solution more stable, I have, by the addition of glycerin, which answers this purpose still better, constructed a formula for a test solution which is entirely stable, simple and rapid in application, exceedingly accurate in results, and, on the whole, admirably adapted for clinical purposes. The formula is as follows: Sulphate of copper, 4.15 grammes; pure mannite, 10 grammes; caustic potash,

20.4 grammes; strong ammonia (sp. gr. 0.880), 300 c. c.; pure glycerin, 50 c. c.; distilled water sufficient to make 1 litre.

The solution should be prepared as follows: Dissolve the sulphate of copper in part of the water and add the glycerin and mannite. In another portion of the water dissolve the caustic potash. Mix the two solutions, and when cold add the ammonia. Finally, with distilled water, bring the volume of the whole to 1 litre and carefully filter.

The principle upon which the application of this test depends is the fact that a solution of cupric sulphate of definite strength, combined as in the formula, is reduced at the boiling point by a definite quantity of grape sugar, causing the complete disappearance of the beautiful blue color and leaving a perfectly clear and colorless fluid as the result. Thus 25 c. c. of this solution are reduced by exactly one-quarter of a grain of grape sugar. The test should be applied as follows: Into a four-ounce glass flask are poured 25 c. c. (f℥vj) of the test solution, to which are added 50 c. c. (f℥jss.) of distilled water, and the whole is heated to the boiling point over a spirit lamp. A pipette, graduated in minims and holding not less than half a drachm, is now filled with the saccharine urine, and as the test solution begins to bubble lightly the urine is slowly discharged from the pipette—drop by drop—into the test solution until the blue color completely vanishes and leaves the solution perfectly colorless and clear. The number of minims it took to discharge the blue of the test solution contained just one-quarter of a grain of sugar. By multiplying this number of minims until the product is 480 (one ounce), the multiple thereof is the number of quarter-grains of sugar to the ounce, which, if divided by 4, gives the number of grains of sugar in each ounce of the urine submitted to the test. Any one may readily prove the accuracy of this test as follows: Bring 25 c. c. of the test solution in 50 c. c. of distilled water to the boiling point in a glass flask. Then fill the pipette with a solution of pure grape sugar in water of known strength—say eight grains to the ounce. Still better is the addition of eight grains of grape sugar to one ounce of normal urine, and as the test solution is slowly boiling discharge the sugar solution from the pipette into the boiling fluid drop by drop, when it will be seen that exactly fifteen minims of the sugar solution completely discharge the blue color of the test solution; therefore fifteen minims of the solution contained one-quarter of a grain of sugar, the exact proportion of a solution of the strength of eight grains to the ounce.

Precautions advised.—In testing, the blue solution should be raised to the boiling point and kept *slowly boiling*, not *violently bubbling;* and the urine to be tested should be *slowly discharged* from the pipette, drop by drop, two or three seconds elapsing between each drop, in order that the precise quantity may be determined which completely eliminates the blue color of the test solution.

The advantages which I have found from this test are:

1. Its rapidity of application. As a rule, the quantity of sugar in a given sample of urine may be determined in from five to ten minutes.

2. Its accuracy. When sugar is present in the urine in the usual clinical range of from two to thirty grains to the ounce, the quantity may be determined within from one-tenth to one-twentieth of a grain.

3. Its perfect cleanliness and simplicity of application. No copper products cling to the utensils (as in Fehling's test) or obscure the chemical reactions from view; and the apparatus is of that simple kind usually kept in the physician's office.

4. Its stability. This solution is quite stable, and, if the bottle containing it is corked to prevent the escape of the ammonia, it will keep almost indefinitely.

I shall have something further to say upon both qualitative and quantitative testing for sugar in urine in my forthcoming work on diabetes. In the meantime, as I have been repeatedly asked for my method of quantitative determination of sugar in the urine, the process is as above given.

Symptoms of Poisoning by Corrosive Sublimate used as an Antiseptic.

Dr. E. W. Mitchell, in the *Cincinnati Med. Journal*, March 15, 1890, says: Since corrosive sublimate is frequently used as an antiseptic it is so important that the practitioner should be familiar with the symptoms of its toxic action. Probably some cases of death resulting from its employment in vaginal or inter-uterine injections might have been avoided if the early symptoms of poisoning had been properly interpreted.

The symptoms which have been observed in obstetric practice are summed up by Dr. Garrigues in a paper in the *American Journal of the Med. Sciences*, on corrosive sublimate and creolin, as follows :

The alimentary canal—thirst, foul breath, metallic taste, red or bluish color and swelling of the gums ; redness, ulceration and sloughing of different parts of the mucous membrane of the buccal cavity ; deep ulcers in the tonsils ; soreness and looseness of the teeth, and sometimes salivation ; vomiting, abdominal pain, tenesmus ; profuse stinking, often bloody diarrhœa. The feces contain mercury. It has been found in numerous cases, after vaginal or intra-uterine injections of a solution of 1.300, followed by the injection of plain water. Even when the solution was so weak as 1.400, it was found in one case, but not in the others. In the majority of cases it is already found the next day ; and it is yet found a long time after discontinuing the use of the bichloride.

The Uropoetic System. There is a marked diminution in the amount of urine, rising to absolute suppression of the secretion. The urine is dark, grumous, contains much albumin, mercury, epithelia cells from the kidneys, and hyaline or granulated casts. The skin is often wet with perspiration, it has been found hyperalsthetic, itching, pale or erythematous. Sometimes there is considerable swelling of the subcutaneous tissue.

The Nervous System. In the beginning the patient is restless, and suffers from insomnia ; later she becomes drowsy, sometimes delirious and finally she collapses. In some cases spasmodic twitchings or cataleptic stiffness has been found in the extremities. The pupils are sometimes contracted as in opium poisoning. Sometimes there is a sensation of being choked. The pulse is rapid and weak, the temperature subnormal. Of these symptoms most characteristic are the diarrhœa, the diminution or suppression of the urinary secretion, the stomatitis, the low temperature and the presence of mercury in the urine and the stools, which may be found by chemical analysis.

The chief changes found after death are hemorrhagic infiltration and extensive ulceration, sometimes diphtheritic patches and sloughs of the large intestines. In some cases a lower degree of inflammation is found in the ilium. Exceptionally the œsophagus has been found inflamed. In some cases there has been found local peritonitis. In the mouth and throat are found the above-mentioned changes.

Another constant change is parenchymatous nephritis. Sometimes deposits of phosphate or carbonate of lime are found in the convoluted or straight tabulæ, but these calcareous deposits are often absent, and may, on the other hand, be found under different circumstances.

In some cases the substance of the brain was found dry ; in others there are extravasations of blood in the meninges.

Aristol.

Aristol (dithymol iodide) is steadily gaining ground as a substitute for iodoform. The following formulæ for its use are quoted from the *Chemist and Druggist*, April 26, 1890 :

I.

℞ Aristol . . . . . 1 part.
Flexible collodion . . . . . 9 parts.

To be used for painting on the skin. Should be dispensed in a dark-colored bottle.

II.

℞ Aristol . . . . . 10 parts.
Olive oil . . . . . 20 parts.
Lanolin to . . . . . 100 parts.

Dissolve the aristol in olive oil and mix with the lanolin.

Bougies are made with cocoa butter, each containing from 2 to 8 grains of aristol. Pessaries contain 6 to 15 grains and are made with the same basis.

Sulpholinic Acid as a Solvent.

According to the *Journal de Médicine*, as quoted in the *Quarterly Therapeutic Review*, Jan. 1, 1890, sulpholinic acid is obtained by the action of sulphuric acid by a complex chemical process on vegetable oils, and is rendered neutral by repeated washings with a solution of chloride of sodium and ether. When concentrated it presents the appearance of a yellowish liquid, with a neutral reaction ; a taste at first sweet, then bitter and astringent. Its specific weight is 1.023. It is soluble in all proportions of alcohol, and miscible with one to two parts of water without losing its oily character. Dissolved in a large quantity of water, it

forms a clear liquid, slightly opalescent, and remarkable for its great affinity for water. It does not decompose, even when heated for some time up to 100° C. At a temperature below 0° C. it is converted into a yellowish mass, which resembles vaseline. It combines with a great number of various substances, which are then either completely soluble in water or readily form emulsions, such, for example, as ether, chloroform, benzine, terebenthine, bisulphide of carbon, oil of mustard and all the etherial oils. Heated or submitted to ebullition, it dissolves numerous organic and inorganic substances, such as sulphur (two per cent.), iodoform (three per cent.), camphor (twenty-five per cent.), naphthalin, chrysophanic acid and numerous coloring matters. These solutions readily penetrate the skin, which completely and rapidly absorbs them. It is thus seen that sulpholinic acid possesses remarkable properties as a solvent, and it is superior to vaseline, oleic acid, glycerine and other vehicles commonly prescribed for external use.

Electricity in Influenza.

Mr. G. Worthington writes to the *British Medical Journal* of May 3, 1890, as follows: "As relapses and fresh cases of influenza are certainly arising, I wish to place on record the very marked benefit derived by my patients by the use of electricity in the neuralgic and rheumatic forms of the affection. In some cases the relief has been immediate and permanent; the pains in the back, groin and sternum, which people have complained of so much, and which have become more or less chronic and defied treatment, have yielded at once to thirty or forty cells of Leclanché's battery."

The Clique of the American Medical Association.

During the Second Day's Session of the American Medical Association's recent meeting, as reported in the *Medical Standard*, June, 1890, Dr. Hooper read the report of the Trustees of the *Journal*, which announced an increased circulation, and favored the continued publication of the *Journal* in Chicago. Dr. Comegys, of Cincinnati, moved that the report be referred to a committee composed of one member from each State and Territory. This was decided out of order and on motion of Dr. Brodie, of Detroit, the report was received. Dr. Comegys then renewed his motion in an eloquent denunciation of the manner in which the *Journal* was run by Chicago and Detroit cliques.

Dr. Seiler, of Philadelphia, seconded the motion in an equally eloquent *exposé* of the absurdities evident in the *Journal's* management. The *Journal* was defended by Drs. N. S. Davis and Shoemaker, after which a motion to table offered by Dr. Keller, of Arkansas, prevailed by a small majority. Dr. Keller, of Arkansas, moved that the constitutional amendment offered by him and adopted some years ago conferring the power of electing their officers on the sections rather than the nominating committee, be annulled and the old rule adopted. He claimed that under the present system some physicians organized as repeaters, went from one section to the other and elected officers.

After a heated discussion, a motion to table, made by Dr. Moyer, was lost by a small majority, the secretary exhibiting peculiar skill as a returning board. Three several points of order directed against the motion and based on its unconstitutional character were made. These revealed the most extraordinary ignorance of the constitution on the part of both president and secretary. Finally it was decided that the motion was constitutionally out of order.

New Hampshire Medical Society.

The New Hampshire Medical Society will hold its ninety-ninth annual meeting in Concord, N. H., on June 16 and 17, 1890. Dr. William Child, of New Hampton, will preside. The programme is an attractive one. Among the papers to be read, we note the following: Beverages of the Past and Present; What shall be the Beverage of the Future—Dr. C. W. Gross, of Milton Mills; Ptomaines—Dr. C. P. Frost, of Hanover; Recent Epidemics of Diphtheria in Keene—Dr. H. K. Faulkner, of Keene; Necrology—Dr. J. J. Berry, of Portsmouth; Medical Men—Dr. Thomas Hiland, of Concord; Railway Hygiene—Dr. G. P. Conn, of Concord.

An exhibition of drugs, chemicals, pharmaceutical preparations, foods, etc., will form an interesting additional feature.

NEWS.

—Dr. Otto Kopetschy, of Jersey City, died on May 29, and was cremated at Fresh Pond, L. I.

—It is reported that a lad, 14 years old, was shot June 7 at Falls of Schuylkill by Dr. E. S. Beary, who mistook the lad for a burglar.

—The ninety-ninth annual meeting of the New Hampshire Medical Society will be held at Concord, N. H., on June 16 and 17, 1890.

—A number of British and American admirers of M. Pasteur, including the Prince and Princess of Wales, have presented him with an album containing their autographs.

—By the will of the late Miss Mary E. Edson, the sum of $10,000 is left to the New York Cancer Hospital; $5,000 to St. Luke's; and $5,000 to the Woman's Hospital.

—Pasteur is reported to have told Miss Kate Marsden, who has been investigating leprosy in Russia, that he can see no ground of hope of making the inoculation process successful in the treatment of leprosy.

—Dr. John S. Butler, one of the oldest physicians in Hartford, Conn., died May 21, at the age of eighty-six years. He was a native of Northampton, Mass., and graduated from Yale College in the class of 1825.

—W. G. Comstock, assistant professor of chemistry at Yale College, while experimenting in the laboratory on Tuesday, burned his hand with a preparation so severely that it will probably have to be amputated.

—The health-officer of Chicago has refused to accept "heart failure" as a cause of death. It is said that 150 death certificates so signed have been returned, with a request for information as to the true cause of death.

—Dr. Perley E. Goodhue, of Haverhill, Mass., died May 19 from malignant diphtheria. He had been attending a child stricken with the disease, and was himself attacked by it in its worst form and died in three days.

—The grand jury made another crusade on June 3, against the adulteration of food in Philadelphia. True bills of indictment were found against six dealers for adulterating, selling and exposing for sale adulterated milk on May 7.

—Sir Morell Mackenzie is said to have been engaged by an American manager to deliver a series of lectures in this country during the coming fall and winter. He is engaged for at least twenty lectures, at the rate of $500 per lecture.

—Chung Lung, a wealthy Chinese physician, 60 years old, was married June 2, in Kansas City, to Ah Gin, a Chinese girl. It is stated that Chung Lung sent to San Francisco for his bride, paying $600 for her to her deputy father or guardian, her parents being in China.

—Dr. R. J. Gatling, of Hartford, Connecticut, desires a contradiction of the report recently sent from Cincinnati to the effect that A. T. Perrine was the inventor of the Gatling gun. Dr. Gatling himself invented the gun, and his letters patent, on file in Washington, are evidence of the fact.

—Surgeon Major G. A. Sternberg, U. S. A., who collaborated with Dr. Findley in getting at the origin, nature, etc., of the yellow fever germ, says Dr. Findley was mistaken in supposing he had solved the problem. The formation that he "got" every time was simply a flaw in the object glass.

—Dr. Arthur H. Wilson, of Boston, died May 11. Dr. Wilson was graduated from Dartmouth in 1863, and became A. M. R. C. S. of England in 1887. He was Assistant Surgeon United States Volunteers from November, 1863, to May, 1866. He practiced medicine in South Boston from 1866 to the time of his decease.

—Scarlet fever and diphtheria are very prevalent in the town of Highlands, near Denver, Col., and the citizens are becoming almost panic-stricken. Among other measures taken to improve the health of the community and to prevent further spread of contagion, warrants have been issued for the arrest of a number of physicians who have failed to report cases of diphtheria and scarlet fever occurring in their practice.

—A recent number of the *Correio Medico*, of Lisbon, tells of the arrest of Dr. Vicente Urbino de Freitas, Professor of Physiology, at Oporto, on suspicion of having poisoned several members of his wife's family. The illness of three members of the family came on after eating sweets and almonds, which were sent to them by post. The total number of murders of which he is accused is seven. The motive for the alleged crime is said to be the acquisition of a large property by the removal of the nearest heirs. Dr. de Freitas is one of the leading members of the medical profession in Portugal.

CH. MARCHAND'S

Peroxide of Hydrogen,

MEDICINAL (ABSOLUTELY HARMLESS)

H_2O_2

is rapidly growing in favor with the medical profession. It is the most powerful antiseptic known, almost tasteless, and odorless. Can be taken internally or applied externally with perfect safety. Its curative properties are positive, and its strength and purity can always be relied upon. This remedy is not a nostrum.

Experiments of Prof. Pasteur, Dr. Koch, and many other scientific authorities, prove beyond doubt that Germs, Bacteria, or Microbes cause and develop: **NOSE, THROAT, AND LUNG DISEASES—Diphtheria, Croup, Sore Throat, Catarrh of the Nose, Hay Fever, Bronchitis, Laryngitis, Pharyngitis, Whooping Cough, Consumption and other Chronic Affections, specific or not.**

GERMS, BACTERIA, OR MICROBES are instantaneously annihilated when brought into contact with **Ch. Marchand's Peroxide of Hydrogen.** This wonderful bactericide acts both chemically and mechanically upon all excretions and secretions, so as to thoroughly change their character and reactions instantly. By destroying the microbian element this remedy removes the cause of the disease.

CAUTION.—I would earnestly impress upon the profession the very great importance of prescribing only my **Peroxide of Hydrogen (Medicinal)**, from which all hurtful chemicals have been eliminated.

By specifying in your prescriptions "**Ch. Marchand's Peroxide of Hydrogen (Medicinal)**," which is sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing my label and signature, you will never be imposed upon.

Prepared only by

Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

A book containing full explanations concerning the therapeutical applications of **Ch. Marchand's Peroxide of Hydrogen (Medicinal)**, with opinions of the profession, will be mailed to physicians free of charge on application.

¼ lb. bottle, retail, 35 cents; ½ lb. bottle, retail, 50 cents; 1 lb. bottle, retail, 75 cents.

SOLD BY LEADING DRUGGISTS.

Laboratory, 10 West Fourth Street, New York.

☞ **Mention this Paper.**

SOLUTION FERROUS MALATE retains its remarkable properties unimpaired when mixed with free acids, such as dilute sulphuric, dilute muriatic, and aromat. sulph. acids.

This acid solution (while it effectually disposes of its objectional properties) has the full therapeutic value of the tinct. chloride of iron, and is equally as good as a solvent and vehicle for sulph. quinia.

Free tannin is incompatible with SOLUTION FERROUS MALATE.

A combination of FERROUS MALATE with Salicylic Acid and Sodium which has been found of great value in obstinate cases of Rheumatism, where other remedies have disappointed. Reports of cases showing remarkably satisfactory results will be mailed on request.

John C. Baker & Co.

PHILADELPHIA.

BURN BRAE

A PRIVATE HOSPITAL

--FOR--

MENTAL and NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

EXTENSIVE AND BEAUTIFUL GROUNDS, affording perfect privacy and pleasing variety. House and surroundings unusually attractive and cheerful. Heat, light and ventilation perfect.

A PLEASANT, SAFE AND HEALTHFUL HOME,

With constant professional supervision. Music, games, open-air amusements, boating, etc., are provided for patients.

THE OLDEST INSTITUTION OF THE KIND IN THE UNITED STATES.

Both sexes received. A limited number of opium habitues admitted. Pleasant companions for female patients.

LOCATED A FEW MILES WEST OF PHILADELPHIA,

At Primos Station, on the Philadelphia and Media Railroad, from Broad Street Station, Philadelphia, Pa.

PROTECTION IN MEDICINE.[1]

BY J. C. WILSON, M. D.,

PHILADELPHIA.

Mr. President: I undertake the honorable duty conferred upon me, Sir, by your distinguished predecessor in office, with commingled feelings of sadness and hopefulness. The sadness is begotten of that sorrow which we all feel for the calamities that befall our fellow-men as individuals; the hopefulness springs from an abiding conviction in the onward progress of mankind as the result of social organization—a progress in which the medical profession has to-day a larger and more responsible part than ever before. Both sentiments are deeply stirred by the circumstances of this meeting. We remember that this Session is an adjourned one, and our thoughts go back to the appalling calamity by which we were prevented from assembling here a year ago. To be present with you some of us have within a few hours traversed a region made forever memorable by sudden overwhelming destruction and death. The mournful anniversary is scarcely past. A thousand hearts, nay ten thousand, are oppressed with the unspeakable sorrow of the events of that fatal day. Within the range of my voice are many whose spirits bear the wounds of that horrible disaster—wounds that will not heal. It is proper that we should mourn. Men of our own profession, men who would have been with us to-day, were swept away powerless to aid their fellows or themselves in that relentless flood. The few who escaped with their lives, true to the instincts of an enlightened humanity and their profession, bruised and battered as they were, spent the remnant of their strength in heroic efforts

[1] The Address in Medicine before the Medical Society of the State of Pennsylvania at its Fortieth Annual Session held in Pittsburgh, June 10, 1890.

to save and succor their more hapless neighbors. And who first to the rescue? From west and east, without loss of time, over obstacles and through hardships of every kind, with food and clothing, with medicines and surgical appliances, with sympathy and cheer, organizing as they came, doing themselves and teaching others what was to be done and how to do it, came those whose vocation in life is to rescue. I look upon their faces now, and their bravery and fortitude, their skill and gentleness, their manliness and honor fire me with enthusiasm. Hero-doctors, we are proud to be of your craft!

Since its organization in 1848 only once before did this Society fail to assemble at its appointed annual meeting. That was in 1861. The meeting then also was to have been held in Pittsburgh. That likewise was prevented by an unspeakable calamity. Men realized that the country was in the midst of civil war; that the integrity of the Union was not only threatened, that had long been the case, but was actually assailed, and already in the greatest danger.

No time then for learned discussion or scientific debate; much less for friendly meeting and the genial interchange of social courtesies. Cherished institutions, property, life itself, were in jeopardy. Men were hurrying to the front for engagement in actual conflict. Those at home were busy with urgent preparations for war. Physicians were needed in hospitals, surgeons on the field of battle. The men who then composed this body, a few of whom are still with us, long peaceful in piping times of peace, were in no mood to sit in grave dispute while their fellows were in action. So the session of 1861 did not take place. Later things were worse, but the following year the remnant of the Society issued a call for the regular annual meeting which was held in Philadelphia.

I allude to these facts not only as being matters of interest in the history of the Society, but also as illustrating a point which serves my purpose.

The two stupendous calamities which prevented these two meetings of our State Society, and made this the fortieth Session instead of the forty-second as it should have been, were calamities of men's own making. Each of them had been long foreseen; thoughtful men had lived in momentary apprehension of their occurrence; plans by which they could have been averted had been repeatedly and earnestly advanced only to be frustrated by the tenacity of vested rights on the one hand, and a temporizing policy of expediency on the other. The one was political, and while I have no disposition to transcend the limits of my theme, I will be pardoned for saying, for the sake of argument, that had the wrongfulness of human slavery been generally recognized in the early days of the Republic, and the subject radically dealt with, the great Civil War would not have occurred.

The other was a calamity of physics, of bad engineering, which would have been averted by doing the right thing when the right thing to do was first known.

Let me say here, that while the right thing often seems to cause some hardships, and expediency has a specious appearance in pleasing everybody; as a matter of fact, everybody is the loser by expediency, and all gain by doing right for the right's sake. Of this more later.

We are not assembled here simply as individuals in search of the pleasures of social intercourse, though in these reunions the renewal of old acquaintances and the making of new friendships plays a large and useful rôle. Nor are we here merely as medical men, who seek in friendly interchange of thought and experience to increase our knowledge and enrich our skill as individuals, though by our good fortune these meetings enable us to do both. We are here as members of a great profession, the organization of which is rendered possible by our organization, and by the relation of this body to the minor societies whose delegates we are, on the one hand, and on the other to the American Medical Association. The stated meetings of these various bodies have an importance not apparent to those who overlook the fact that they are the functions by which the profession as an organized body manifests its life. Without them, disintegration. With them, interdependent life, ceaseless activity, a purposeful and powerful profession, noble in itself, and capable of the highest usefulness to the Society in which it exists, and of which it forms an honorable part.

Forty-two years ago a little group of earnest men organized the Medical Society of the State of Pennsylvania. To-day its members and delegates comprise the greater part of the profession of the State. We are a harmonious body. If there be differences, they relate to details rather than to princi-

ples. We are in close accord among ourselves that our influence must be exerted in the direction of broader knowledge and higher skill among the members of our profession, and in the direction of the highest dignity, the greatest good, and that consistency which commands respect, on the part of the profession itself.

To realize these aims we must see to it that the profession is protected. It requires protection both within itself and in the approaches to it.

I venture to depart from the customary form of the *Address in Medicine*, to bespeak your attention for a few moments to this subject. Protection in medicine is a necessity that needs no argument. It is necessary to the very existence of the profession itself. That this is well understood is shown by the stringent safeguards by which medicine is surrounded in older and more disciplined countries than ours, where certain social problems now engaging our attention have been thoroughly worked out, and by the efforts made in this direction by the profession in this country from the earliest days. It is necessary in a far higher degree to the public, who are the real sufferers from unrestricted license and free trade in matters that touch the general and personal health. But the public is apathetic in this matter. The cares of this world, the pressure of affairs, the mysticism of quackery, the allurements of charlatanism blind the attention of the people to evils that largely affect their lives and happiness—yet more, if it were but known, their pockets.

The very fact that a diploma is esteemed a necessity to the practitioner shows the universal demand for some sort of evidence that the doctor knows something. But there are diplomas and diplomas, just as there are colleges and colleges.

The demand creates the supply. The possession of a sheepskin no more certifies to learning than a new suit of clothes indicates riches. Both can be had for a small sum of money and each often represents the total assets of the owner. The protection afforded by a diploma is in fact no protection at all. At this point we encounter the power of vested rights. Many of the colleges insist that the degree which they by virtue of their charters confer, and the diploma which attests the fact, have always conveyed and must still continue to convey the license to practice; and the poorer the college and the larger the proportion of its graduates to matriculates, the louder the clamor, and the fiercer the opposition to measures of reform.

The next step in the direction of protection is registration. By this means itineracy is hampered. The possession of a diploma or the experience that comes of a number of years of practice without one, are requisites to practice under the registry laws. But the vital question of proficiency, even of a minimum technical knowledge is not touched. The Registrars in most cases have neither the knowledge nor the power to discriminate as between the colleges granting diplomas; they are only required to know that the colleges have been legally incorporated. Where, as in the State of Illinois, the graduates of *Colleges not in good standing* are not granted a license without examination, the schedule by which the standing in different institutions is rated is absurdly low. (See Report of the Illinois State Board of Health, 1889.)

There remain two other plans of Protection in Medicine, both of which are now undergoing trial on this continent, with encouraging results. These are: first, the appointment by the State or by the proper authority within the State, of a board of examiners to examine irrespective of diplomas the candidates for license to practice; and second, the organization of the entire profession in each State into an electorate, which shall send representatives to a central body having full control of all questions relating to medical education, examination, registration and license.

Under the first of these plans the entire question of registration is placed in the hands of the board of examiners appointed by the Governor or by the State society. It is obvious that such a board, to be effective, must constitute the only means by which an applicant can obtain a license to practice. There are now in the United States twelve licensing and examining bodies that do not give instruction. The practical working of this plan as shown in North Carolina, Virginia, Minnesota and other States, presents few difficulties, and it constitutes an effective barrier against the inroads of poorly qualified holders of diplomas. The duties of such boards are clearly defined and their operation is simple and effective. There is no doubt that in the course of a short time this plan will be widely adopted. As Dr. Rauch, Secretary of the State Board of Health of Illinois, has shown in his last report, the

operation of this plan has already been productive of beneficial results not only upon the profession itself, but also in the general tendency among the colleges in the direction of raising the standard and lengthening the term of study. The obvious defects of this plan are, first, that its powers are too limited, there being no control of preliminary and special education; and, second, that the appointment of boards is liable to non-professional political influence. The records of the State Medical Board of Virginia for four years ending October, 1888, illustrate the efficiency of this plan as compared with former methods. Of 240 candidates presenting themselves for examination and holding diplomas, probably of colleges in good standing, 54 or 22 per cent. were rejected. Those who advocate this plan know that Dr. Rauch, to whom all praise is due for his earnest and efficient labors in the cause of an improved medical education, has urged the establishment of a uniform series of regulations for examining boards in all the States throughout the country. Notwithstanding the rapid increase of population in some of the more newly settled States, and the rapid tendency to uniformity of social organization, the day must be far distant when uniform requirements for the practice of medicine throughout the land will be either practicable or endurable. The boundaries of the States define territory sufficiently large for uniform regulations upon this subject. Each State should define requirements in accordance with the necessities of its population. Practitioners desiring to establish themselves under the jurisdiction of a new board must prepare themselves to meet the requirements of the new board, and pass its examination.

The second plan is less generally known although it has been tried for many years in the Province of Ontario, Canada. It was fully described by Osler in an address entitled "License to Practice,"[1] delivered to the Medico-Chirurgical Faculty of Maryland in the spring of last year. My account of this plan is drawn largely from Prof. Osler's address. It appears to me so practical, so closely in accord with the requirements of the profession and so completely to meet in every particular the difficulties of protection in medicine that I am surprised that it has attracted so little attention in the general discussion of the subject.

To carry into effect such a plan would demand the enactment of laws meeting all its requirements and a general act of incorporation of the profession as a body in each State. It is desirable not only in theory but in practice that the State Board should be composed of representatives from electoral districts rather than appointed by the Governor or the societies. Such a board should have full jurisdiction of all matters appertaining to medical education. The counties or other territorial districts which might be made, should send a limited number of representatives to the Board, depending upon the population of each district. The electors and, as a matter of fact, the representatives would be constituted by registered practitioners irrespective of schools. The Governor of the State would issue the first warrant for the election, which would subsequently be the prerogative of the executive of the Board. The number of representatives should be determined by the medical constituency in each electorate as previously arranged. Representatives should be elected for a term of four or five years, and members should be eligible for re-election. Universities and schools should be fully represented on the Board. It would be necessary to return members from each of the generally recognized divisions which at present constitute practitioners. There would be active electioneering and a good deal of log rolling, some political trickery without question, but I agree with Osler in thinking that on the whole that it would be found that such an election could be conducted with tolerable purity. To such an organization might be safely entrusted the full control of all questions relating to medical education in the State, and, within certain limits, questions of public health. It would correspond to the Synods and Conferences of the various religious denominations, with powers accurately defined by legislation, including the right of appeal to court for the infliction of certain penalties, such as the revocation of the license to practice in flagrant cases. The important ordinary duties of such a board would comprise the regulation of the requirements of matriculates; the course of study in the colleges; length of terms; the final examination of applicants to practice and the granting of the license. The necessary expenses would be met, first, by the fees to be paid by the candidates for examination, and, secondly, by a small annual tax levied upon all registered practitioners. Such bodies would, in a brief time, become

permanent establishments in the States, with buildings properly equipped for examinations, the necessary arrangements for conducting in an orderly and systematic manner the business of the profession and a permanent resident secretary. Such boards would determine the minimum standard of education necessary to enter upon the study of medicine, and in so doing would establish a guaranty of uniformity which cannot be expected in the schools. For the preliminary examinations independent teachers would be preferable to professional men, and the examinations should be held in different parts of the State. Such examinations would effectually prevent the entrance of men lacking the early training requisite for professional study.

I refer, at this point, to the subject of expediency. The hardship of preventing an ambitious but ignorant man from entering upon the study of medicine is apparent rather than real.

There would be, as a matter of course, great diversity of opinion in regard to the selection of the examiners for license to practice. The difficulties in this direction arise from the want of suitably trained men outside of the teachers in the schools, but those difficulties are not insurmountable. By systems of numbers for written examinations, and the presence of two examiners at all oral examinations impartiality would be secured. In the scientific branches it would be almost impossible to find in the general profession examiners having the necessary training; on the other hand, there are an abundance of men in every State fully capable of conducting the examinations upon the clinical branches. The difficulties relating to the differences between the various schools of practice, which at present seem to many insurmountable, are rather imaginary than real. A uniform series of examinations in anatomy, physiology, chemistry, pathology, morbid anatomy, practical obstetrics, surgery and medical jurisprudence should be passed by all applicants. In the subject of therapeutics only should there be different examiners to meet the requirements of the schools. Upon application it would be necessary for the student to indicate whether he desired to apply for an examination in therapeutics as a regular, as a homœopath, or as an eclectic, and if successful his name should be placed upon the State register in accordance with his choice.

In regard to the working of this plan in the Province of Ontario I quote the following statement from the address of Prof. Osler. "It practically hands over to the profession, through the elected representatives, the management of their own affairs so far as they relate to preliminary and professional examinations and certain disciplinary enactments. In spite of the strenuous opposition on the part of many who felt that it was a most degrading thing thus to lop the important privilege hitherto held by the Universities which enabled graduates to obtain license without further examination; in spite of dissensions and dissatisfaction such as are almost inevitable in connection with a new organization, the Board has persisted in its good work and to-day, after 23 years of existence, it has a record of which the entire profession of the Province is most justly proud. On no point was opposition more bitter or more prolonged than on the admission to representation of members of the homœopathic and eclectic bodies. But wise counsels prevailed and representation remained general, as it was, though it is true, I believe, that the eclectic body no longer has practitioners enough in the Provinces to send a representative.

"The influence which this organization has exerted has been in the highest degree beneficial, and the schools now accept the inevitable with a perfectly good grace. The Board possesses a magnificent central building in which to conduct the examinations, with offices for registration, and rooms for a Provincial Library. The fees from the examinations and a small annual tax levied on each registered practitioner has proved a source of ample income. The same condition, with modifications, exists in the other British Provinces."

One or the other of these plans, perfected in detail or modified to meet practical requirements is urgently needed by the profession of this State. To secure the enactment of the requisite laws we must have a united profession. Unanimity means concession. In this matter concession must be in the direction of the public welfare. I believe the colleges are ready; I know that many influential members of the faculties of the more influential schools are earnest advocates of reform. The material interests of our schools will be substantially furthered by measures which will effectually end the competition of the cheap two-term schools of neighboring States. But higher motives carry greater weight.

Hereafter the diploma will be a less imposing document. It will become a certificate of scholarship, valuable only in proportion to the standing of the school by which it is issued. License to practice will be granted only to those who are proficient without regard to the school in which technical knowledge and skill have been acquired. Examinations will not be too rigorous; no catch questions will be permitted; and fundamental knowledge only will be required.

There must be, however, no talk of concessions to those who delight in calling themselves eclectics and homœopaths. Their representations must be of right. Their rights under the law are the same and equal with our own, and must be at once and fully recognized—but no more. In the wholesome atmosphere of higher knowledge the fetich of names and the shibboleth of dogmas will lose their fascination.

The long work of our Committee on Medical Education is about to bring forth fruit. The times are ripe. Upon us rests the responsibility of throwing the influence of a united and harmonious profession into the final struggle. I fear no great catastrophe, we shall have neither internicene war nor irruptions of Goths and Vandals, but the open gateway to the medical profession is an abiding calamity to a great commonwealth.

ABORTION FOLLOWING THE GRIPPE.

BY CLARENCE KING, M. D.,

PHYSICIAN AND SURGEON TO THE CATTARAUGUS CO. INSANE ASYLUM, ETC., MACHIAS, N. Y.

In the MEDICAL AND SURGICAL REPORTER, April 26, 1890, I notice a communication from Dr. W. D. Banks, of Mifflintown, Pa., detailing the history of several cases of abortion following the grippe, which have occurred in his practice. His experience has been so nearly identical with mine that it may appear superfluous for me to narrate the following cases; yet, as the relation between the diseases and abortion has not apparently been observed by the majority of physicians, I am induced to report my observations.

The epidemic reached our town about the first of January, and spread rapidly, being at its maximum during the month of February. Since that time I have had several cases illustrative of the tendency which the grippe seems to have to producing abortion, and know of other instances where this has occurred in the practice of my professional neighbors. This list includes all the cases of abortion or threatened abortion which have come under my care since the outbreak of the epidemic; and I have not had a case of the grippe in a woman in which I have become aware that pregnancy was present that is not mentioned in this paper. These cases were widely separated geographically, in distant parts of the town, and occurred during a period of about nine weeks from first to last. They all, however, followed the grippe in from seven to fourteen days, and if there was any other cause to account for the premature termination of pregnancy in any of the cases, I failed to discover it.

Case 1. Mrs. F. L., multipara, third month of pregnancy, had had one abortion about three years ago. She had the grippe about the middle of January, and on the thirtieth was taken with a dull aching pain in the bowels, which she at first attributed to constipation. February 1, pains became more severe, and when I saw her the fetus had been expelled. The afterbirth was removed instrumentally, and she made a good recovery.

Case 2. Mrs. A. K., multipara, third month of pregnancy, had never had an abortion. Her two children were very sick with influenza and she became very much exhausted in caring for them. Before they were well she was taken sick with the disease and had very violent coughing spells and high temperature. Abortion did not occur until nearly two weeks after. The fetus was expelled with very little pain or hemorrhage, but the afterbirth was left behind and I removed it with forceps.

Case 3. Mrs. E. S., 20 years old, primipara, healthy, four or five months pregnant, had been troubled a great deal with nausea and faintness and other subjective evidences of pregnancy. About March 20, she was taken with the grippe, the attack lasting about a week. April 9, labor-pains came on, and within a few hours, while at stool, she expelled the fetus with the sac unruptured. Part of the placenta was also dragged away with the fetus. I removed another portion of the placenta with forceps, but, owing to to the difficulties present, I did not get it all away. Another fragment was expelled a few days later. The patient made a good recovery.

Case 4. Mrs. A. J., about 28 years old, multipara, had never had an abortion. Her menses ceased about six weeks before her attack of grippe, which was not very severe. A few days later she was taken with paroxysmal pains in the bowels with some little "show." Under rest and opiates the pains finally ceased and gestation has continued without interruption.

Case 5. Mrs. I. S., 22 years old, mother of four children, was in the ninth month of her fifth pregnancy when she was taken with the grippe, but she did not have a very severe attack. In a few days she was taken with severe abdominal pains and, thinking "her time had come," she sent for me. I found the os dilated so as readily to admit the finger, but the pains gradually wore away, and she carried the child for three weeks before being confined. With her other children she had never been troubled with false pains, and in this case she had distinct though feeble uterine contractions.

Case 6. Mrs. G. R., strong and healthy, mother of two children, had never had an abortion. Her last menstruation was about six weeks before she was taken with the grippe. She suffered quite severely with pain in the head, back and limbs, and had high fever. Soon after getting better she aborted. The fetus was about an inch long. She had considerable hemorrhage, and I removed the membrane with the hand. The patient made a good recovery.

Case 7. Mrs. W. H., mother of two children, had had one abortion. When about three months pregnant she had the grippe, and ten days later she was taken in labor. The fetus was expelled after about forty-eight hours, and the placenta a few hours after.

Case 8. Miss V. C., primipara, about six weeks pregnant, had had the grippe nearly three weeks before she "came around." The fetus was expelled with some pain and profuse flooding. Recovery was good. I have no reason to think this was not an accidental abortion, as the patient was underwitted and was closely watched, day and night, for two weeks before the abortion occurred.

Invention of the Microscope.—The third centenary of the invention of the microscope will be celebrated this year at Antwerp, where a historical exhibition of microscopes will be held.

THE THERMOMETER IN OBSTETRICS.

BY PETER McCAHEY, M. D.,
PHILADELPHIA.

The importancc of thermometry in obstetrics cannot be over-estimated. In medicine the thermometer is the infallible guide of the physician; but in the lying-in room it is of especial value. Unfortunately it is seldom used there, except to mark the progress or decline of the diseases of the puerperium. And yet its early use, its routine use, before delivery, even before labor has begun, is of the utmost importance. If the temperature of every pregnant woman were ascertained before delivery, thousands of cases of so-called puerperal fever would be correctly diagnosed as typhoid fever, or malarial fever, and much suffering would be avoided, many lives would be saved and many professional reputations would be preserved.

It must be remembered that pregnant women are as susceptible to the poison of typhoid fever or malaria as are any other persons; and if it be true that exhaustion renders the system less able to resist these poisons, then they are more susceptible to them than others; for, in some cases, no exhaustion can compare with that which is incidental to the pregnant state.

Under the present method of managing obstetric cases a woman who has contracted malaria or who is developing typhoid fever is taken in labor. She is attended by a midwife who never saw a thermometer, or by a physician who never uses one unless a patient is "sick." Her quickened pulse is regarded as due to "nervousness" or the "progress of labor." Lack of appetite, headache and other evidences of ill-health, of which she may have complained to her friends, are ascribed by them to her pregnancy and are not mentioned by her to the physician if there be one in attendance. In a few hours labor is over. The loss of blood accompanying it and the ensuing uterine involution acts as an antipyretic and masks the fever for a time; but the disease persists, and, in a few days, breaks out with renewed force.

The physician is hurriedly sent for, and when he arrives he finds all the symptoms of elevated temperature and he *then* uses the thermometer. The family demand to know what is the matter, and as the

patient has a "fever" and is in the puerperal state, he is reluctantly compelled to inform them that she has "puerperal fever." If the family are familiar with the latter-day teachings of some eminent obstetricians, who say that puerperal fever is never autogenetic, they will charge that the fever was carried to the patient by the physician, and he falls several degrees in their estimation. Should the case result fatally he is, to a certain extent, held responsible by them for the woman's death.

In the meantime the physician believing the fever to be essentially a "puerperal" one proceeds to vigorously attack the germs which he imagines are lodged somewhere in the uterine cavity. Gallons of strong solution of bichloride of mercury are injected into that part of the body, regardless of the danger that the bichloride may have a stronger affinity for the tissues than for the water in which it is suspended, and he may leave it to be absorbed by them and cause the very death that it was employed to avert. In many cases it does produce an irritative inflammation, increasing, instead of lessening, the fever. This, in turn, is taken to mean an invasion of a fresh area by the germs, consequently more injections are given and a still higher fever results. So the vicious circle widens until the grave is reached.

How different would be the result if the thermometer were uniformly used at the first visit, as advocated in this paper. If at that visit, the temperature were found to be above normal, the patient or her friends would be told, at once, that she had a slight fever, and the appropriate medicines—aconite, veratum or quinine—could be ordered immediately, regardless of the state of labor. After delivery the medication would be continued, and if the fever remained, preparations would be made at once to treat a prolonged disease. It would be known that the fever was not due to the entrance of germs into the uterine cavity, as the disease was detected before that cavity was opened, and no uterine injections would be used. The family would not be unnecessarily alarmed by the frightful term of "puerperal fever," and the physician's reputation as a skilful guardian of his patient would be increased and not lessened.

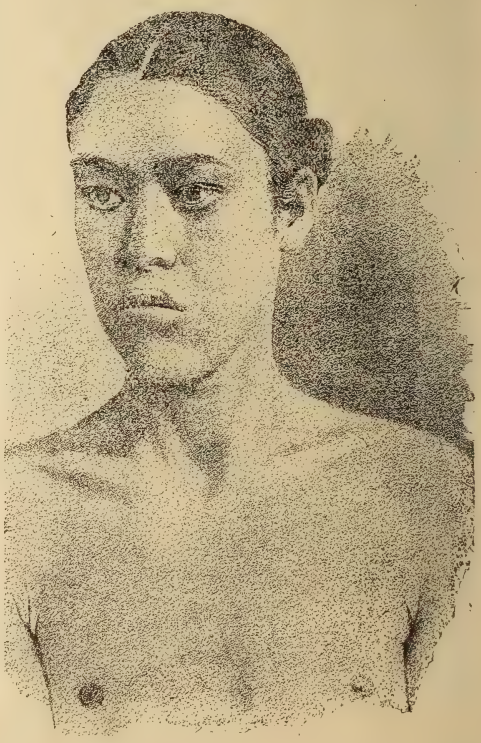
Above all, as a correct diagnosis had been made, no time would be lost in instituting appropriate treatment, and the probability of recovery would be much greater than under the old method of waiting for a week and then injecting, in the dark, antiseptics intended to destroy germs that did not exist, or prescribing the latest novelties for a disease foreign to that with which the patient was affected.

304 North 18th Street.

HERMAPHRODITISM IN THE MALE.

TRANSLATED BY ENRIQUE SOLÓZANO, M. D.

On August 4, 1889, a person named Guadalupe Vargas was brought to the Seventh Station of Police in the City of Mexico, charged with rape, by Vicente Rodriguez. It seems that the day before Guadalupe Vargas took a walk with "la Rodriguez," and they both became intoxicated with pulque. When the evening came "la Vargas" proposed to "la Rodriguez" to sleep in her room; and the latter did not object, as they both were women.

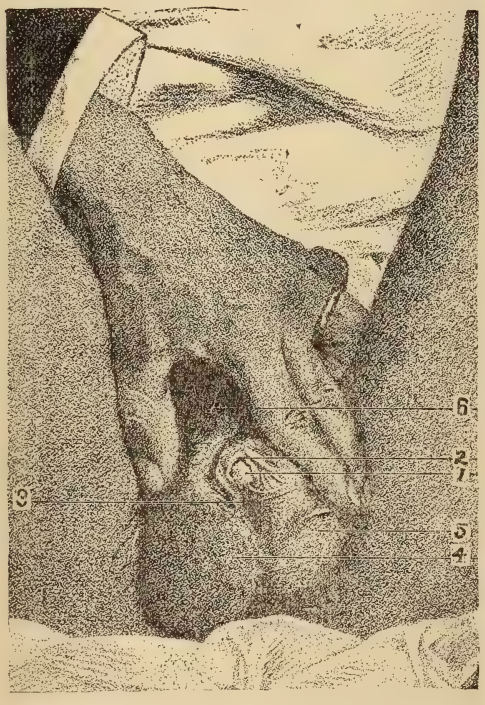


As soon as they went to bed, la Vargas tried to have connection with la Rodriguez, which produced a scandal and caused la Vargas to

be taken to the police station. An examination was made by Dr. Araujo, who did not find sufficient cause to hold la Vargas in prison, and she was released. Later on Dr. Egea heard of the case and found that the person Vargas had had, when younger, an attack of the measles and had been left almost an idiot, deaf and unable to speak clearly, and so he could not get very much direct information about the case.

Vargas was supposed to be a woman, 22 years old. When born the mother, ignoring its true sex, dressed the child as a girl. At present Vargas is tall, slender, with rather feminine features, a form like that of a man and a voice like that of a woman. There is sexual attraction towards women. In the sexual orgasm ejaculation takes place through an inferior opening similar to that found in all cases of hypospadias.

The circumference of the pelvis measures 86 centimeters (34 inches); the length of the penis seen in the illustration, in repose,



is 3½ centimeters (an inch and a half); it has no urethra, but is covered with a well-formed prepuce, and the two corpora cavernosa, can be easily felt. The circumference of the penis at the root is 4½ centimeters (an inch and three-quarters). The circumference of the corona is 3 centimeters (an inch and a quarter). The length of the perineum is 6 centimeters (two and a half inches). The distance from the root of the penis to the opening of the supposed vulva is 2½ centimeters (one inch). The antero-posterior length of the opening which simulates a vulva, is 3 centimeters (an inch and a half). The depth of the opening, measured with a female catheter, as the finger causes great pain and does not reach the bottom, is 8 centimeters (three and one-eighth inches). By rectal touch it was easily ascertained that there was no uterus, but there was a prostate gland about the size of a chestnut. A male catheter was introduced into the bladder and a quart of urine was extracted. The scrotum contained testicles, each of fair size. The mons veneris was well covered with hair.

From the description and by the aid of the illustrations which have been reproduced from the *Gaceta Médica*, of Mexico, April 15, 1890, it will be seen that this was a case of hypospadias with a rudimentary penis.

Society Reports.

PENNSYLVANIA STATE MEDICAL SOCIETY.

Fortieth Annual Meeting, at Pittsburgh, Pa., June 10 to 13, 1890.

First Day, June 10.

The President, Dr. J. B. Murdock, of Pittsburgh, took the chair and called the meeting to order, and the Rev. David Jones, D. D., made the opening prayer.

Dr. E. A. Wood, of Pittsburgh, then delivered the

Address of Welcome.

In it he made a plea for the exchange of views and experiences of different medical men, and for the support of medical societies—County, State and National. He pointed out the error of the notion that the societies are for the physicians of the larger towns and not for country practitioners, and advocated a fuller representation of the actual experience of the country physicians who often, from modesty, keep back.

Dr. Wood then stated that the physicians of Johnstown requested that one of their number be allowed to present a brief paper.

On motion rules were suspended.

Dr. George W. Wagoner, of Johnstown, then, for the Cambria County Society, testified to the noble charity of the physicians of Pennsylvania, whose members are represented in the Society. He described the horrors of May 31, 1889, when flood and fire devastated Johnstown, and the remains of memory and the reproduction in dreams which still linger amid the inhabitants. He spoke of the prompt and full sympathy with which the State and the country responded to their need, and the first help and money brought from Philadelphia by Doctors Mills and Mays, and the large appropriation of the State Medical Society. After a graphic account of the first medical effort at Johnstown, he said that no member of the Cambria Society deserted his duty, no matter how great his bereavement; and helpers from other parts of the State came to the help and rescue of their brethren at Johnstown. He paid a special tribute to the work of the Philadelphia branch of the Red Cross Society and its leader, Prof. Pancoast, which organized a hospital, maintained it for a long time and then turned over the property to the Cambria County Society, which has been enabled to perpetuate the hospital and to continue the work it began. After this followed a warm tribute to the memory of Drs. H. W. Marbourg, J. C. Wilson and G. C. Brinkey, who were members of the Cambria County Medical Society, and a fair tribute to the three homœopathic physicians who lost their lives at the same time.

The total amount of money contributed by the various county societies in Pennsylvania, and distributed at Johnstown, was $8,419.23.

Dr. Wagoner's address was then referred to the Publishing Committee and ordered to be printed.

Dr. Edward Jackson, of Philadelphia, reported the meeting of the American Medical Association and suggested the organization of State delegation at time of meeting of the State Society, and that this should not be postponed until the time of meeting of the American Medical Association.

Dr. Jackson then read, for Dr. Allis, the

Treasurer's Report.

Dr.

Cash on hand at beginning of present year,	$1,636 33
Receipts for fiscal year,	2,128 90
	$3,765 23

Cr.

Expenditures,	$3,566 71
On hand,	198 52
	$3,765 23

The small balance left over was due to the fact that last year the Society (in its short meeting) had voted $1,000 to the sufferers from the Johnstown flood. The report called attention to the fact that some county societies pay their assessments promptly and that all should do so. The Treasurer reported that the county society of Lackawanna had not paid at all, while the Snyder County Society had paid only a part of its assessment.

Dr. Bishop moved that the Secretary be requested to present a report of the meeting of the State Society in 1889, and that this report and that of the Treasurer be referred to the Auditing Committee. Carried.

Dr. Jackson read the report of the Publication Committee, announcing the printing of 2,353 volumes, at a cost of $1,322.56. $135 of this expense was for maps of one paper. Seven counties, the report said, did not attempt to furnish lists of registration of physicians as provided in the rules of the Society.

Dr. Allyn, of Allegheny County, read a carefully-prepared report of Allegheny County Medical Society, with a full account of the Johnstown disaster. The report was referred for publication to the Publication Committee.

Dr. E. A. Wood called attention to report of the proposed Constitution and By-laws for Society.

Dr. Dulles then moved the adoption of the resolutions proposed in its report by the Committee on Publication:

I. That hereafter every motion directing an expenditure of funds, shall appropriate a definite, carefully-estimated amount or so much thereof as may be required for the purpose indicated. And that all appropriations of money not accompanied by such an estimate of amount shall be referred to the Publication Committee.

II. To omit publication of list of registered members in the Transactions.

III. That the resolution requiring the printing of the original programme of the meeting of the Society in the Transactions be rescinded.

The resolutions were adopted.

Dr. E. A. Wood moved that all resolutions that have just been passed be referred

to Committee on Constitution and By-laws, that they may be incorporated in the Report of that Committee Carried.

Afternoon Session.

Dr. James C. Wilson, of Philadelphia, delivered the

Address in Medicine.[1]

In opening he referred to the heroism of the medical men of Johnstown at the time of the flood last year, and alluded to the postponement of the meeting which was to have been held in 1862 in connection with the postponement of that of last year. From the cause of both postponements he drew the moral that damage comes from preferring expediency to principle. From this he urged the importance of protecting the community from imperfectly educated physicians, and the depriving the diplomas of medical schools of the character of licenses to practice. He discussed the appointment of State Boards of Examination and a plan for their selection.

Dr. T. J. Mays, of Philadelphia, read the

Address on Hygiene.[2]

He discussed the relation between artificial inoculation and pulmonary consumption. He argued strongly against the theory that phthisis is a contagious disease—in the usual acceptation of this term—and cited the experience of a number of hospitals for consumption and statistical inquiries in Europe to support his position.

Dr. Ernest Laplace (a guest of the Society) described, at length, the fundamental facts of experimental investigation of tuberculosis, referring to Villemin and his injections and Koch's discovery of bacillus.

Dr. Flick called attention to a few points of what he called sophistry in Dr. Mays's able address. If tuberculosis is a contagious disease preventive measures will prevent its spread. Such measures are adopted in all well-regulated consumption hospitals and, therefore, nurses and doctors don't often get consumption.

Dr. J. C. Wilson assailed the fundamental proposition of Dr. Mays's paper that if a disease be contagious those most exposed will be most liable to contract it. Scarlatina is unquestionably contagious and yet none of us will admit that those most exposed to it are most likely to contract it. This he attributed to natural insusceptibility and acquired insusceptibility by a previous attack. Similar insusceptibility is found in the case of tuberculosis. Dr. Mays's statistics, he said, are cited in such a way as to furnish *ex parte* evidence and do not justify the conclusions to which he comes.

Dr. John Aulde emphasized the insusceptibility of certain persons to tuberculosis. He would use the word "contactuous" in describing this occasional mode of communication.

Dr. Dulles said that his opinion is substantially that expressed by Dr. Mays and Dr. Aulde. He said that, if there is any value in definition and in having fixed meaning in scientific terms, it is not proper to apply to tuberculosis the term contagious. He had gone over the evidence with care—without entering into any public discussion in regard to it—and had come to the conclusion that the argument of those earnest and conscientious men who believe tuberculosis to be contagious do not prove this to be the case.

Dr. Mays closed the discussion and said his statistics were carefully and impartially collated and his fundamental proposition that those most exposed to a contagious disease are most liable to contract it had not been weakened at all by what Dr. Wilson had said.

Dr. J. M. Batten, of Pittsburgh, read a synopsis of

340 Cases of Labor,

containing an interesting summary of his experience in confinement.

Dr. D. Longaker spoke on the subject, and advocated early use of forceps.

Dr. Dunmire asked how many still-births occurred in the cases in which Dr. Batten used ergot?

Dr. Batten replied.

Dr. Blackwood announced that he had a charge against a member whom he did not name, and moved that it be referred to judicial council. The motion was carried.

The Secretary read an invitation from the Mississippi Valley Medical Association to attend its next meeting, which was, on vote, accepted.

The Secretary read an invitation from the

[1] Published in full in this issue of the Reporter.
[2] Published in full in the Reporter June 14, 1890.

Berks County Medical Society to the State Society to hold its next meeting in Reading. On motion, it was referred to the Committee on Nominations.

In accordance with the resolution of the morning session, Dr. Atkinson, Secretary, read a report, in the form of minutes, of the meeting of the Society in 1889.

Dr. Bishop moved these minutes be approved and the action of the meeting be confirmed.

Adjourned.

In the evening Dr. Murdoch, of Pittsburgh, delivered his

Presidential Address.

He said that when a year ago details of the Johnstown disaster were coming in, resolutions were adopted that emptied the treasury and the Society adjourned its meeting, and that the history of medical societies has no brighter page than the extension of help and sympathy to suffering brethren. Every year advances of the medical profession were made and a yearly pilgrimage was made to some convenient point, where scientific views could be exchanged. He spoke of the danger of quacks and the value of the services of regular physicians.

He expressed an unfavorable opinion of the principle of the Medical Examiners Board and recommended the abrogation of restrictive laws, holding that the sooner the medical profession is rid of the legislative ideas governing it the better. The profession, however, should keep its skirts clear of any irregular practice of any description.

Second Day, Wednesday, June 11.

Morning Session.

Dr. Flick moved the Réport on Hydrophobia which the Society in 1888 asked Dr. Dulles to make, be made after the Address on Laryngology. Dr. Daly being absent, the Report was called for at once, and

Dr. Dulles then spoke on

Hydrophobia.

He referred to a case of so-called hydrophobia in New York, June 9, and attributed the death to fear, the statement of the physician to the patient that he had hydrophobia, and to the use of restraint, morphia and chloroform in Bellevue Hospital.

He then spoke of the increase of cases of hydrophobia and of the fear of it in countries where Pasteur Institutes were established, and regretted that two such institutes had been recently established (one by Gibier, in New York, and one by Lagorio, in Chicago), and that already the cases of supposed hydrophobia and of danger of having it had multiplied enormously. He said that formerly there was hardly any hydrophobia in the United States; and medical men could not be indifferent to the effect of these institutes. He also spoke of the great amount of hydrophobia in France, where Pasteurism prevails, and the almost total absence of it in Germany, across the Rhine, where Pasteurism is not accepted. He strongly deprecated an attitude of indifference towards these circumstances and the possible effect of the introduction of Pasteurism in America.

Dr. Laplace said that scientific discussion of the Pasteur method is out of date. The absolute results of inoculation which causes death with absolute certainty in every case in 8 days—or 11 days—proves this, and settles the question. As to the results of Pasteur's method, he said in Russia, before Pasteur's method was used, 83 per cent. of all peasants bitten by a rabid wolf died of hydrophobia and now only six per cent. die. He denied the truth of statistical statements by Dr. Dulles and said that the difference between France and Germany was due to the fact that in Germany all dogs are muzzled. He also said that persons who had not made experimental inoculations had no right to express opinions about the subject.

He said that Victor Horsley and other investigators of England had repeated all the experiments of Pasteur and confirmed his conclusions. He was so convinced of the danger of hydrophobia and the efficacy of Pasteur's method that, if bitten by a dog, he would rush to Pasteur or to Gibier.

Dr. Early reported a case of spurious hydrophobia.

Dr. Hanxt said he had been to Paris and been told that Pasteur only inoculated those who were bitten by dogs certainly rabid.

Dr. Dulles, in replying, regretted that the correctness of his statements had been called in question by Dr. Laplace, and asserted their accuracy and reliability. He objected to the style of Dr. Laplace's criticism, as shown in his sneering comment the day before on the argument of Dr. Mays in regard to the non-contagiousness of phthisis, and as exhibited to-day in commenting on

the remarks on hydrophobia and Pasteurism. He also took up the fact, which Dr. Laplace admitted, that there was almost no hydrophobia in Germany, and asked how much better to have the muzzle and no hydrophobia than to have Pasteur and more of it than was ever known before. He deprecated the supercilious attitude sometimes assumed by laboratory experimenters to those who were engaged in actual practice, and the exclusive manner in which they insisted upon notions derived from the study of disease in test-tubes and rabbits and white mice. He asked if Dr. Laplace still believed in the Brown-Séquard testicular therapy.

Dr. Love, of St. Louis, was by vote invited to take seat on platform.

Dr. W. H. Daly, of Pittsburgh, read the

Address on Laryngology,

in which he opposed the influencing of young men by those older, and intimated that he had had actual experience in being overawed and controlled by men who acted as despots to younger men. He urged independence of thought and action upon the younger members of the profession. He referred to the conflict over the case of the Emperor Frederick and deprecated the professional quarrel which arose over it. He said he knew Dr. Morrell Mackenzie and praised him highly. He expressed again his opinions in regard to the proper treatment of hay-asthma by putting the intra-nasal tissues into a healthy and normal condition.

Dr. J. A. Lippincott, of Pittsburgh, showed and explained the use of an

Intraocular Syringe in Cataract Extraction,

made of glass and soft rubber. He spoke of the advances made from time to time in the methods of medicine and surgery, and especially of the improvements in the operation for cataract as devised by the immortal Von Graefe. The most important was the introduction of fluids into the anterior chamber after removal of the lens. He began to practice this in 1888 and since then has applied it to 57 cases. The results were very satisfactory and obviated certain disadvantages of the usual method.

Dr. Lawrence Flick read the

Report of the Committee on Medical Examiners,

reciting the history of the bill which was presented to the Legislature of Pennsylvania, and reporting the names of members of the Legislature who voted against the bill.

Dr. Roberts moved that the report be accepted and published in full in the Transactions and that the appropriation asked for be granted—$104.10.

Dr. Dulles moved that in printing the report the record of votes in the Legislature be not printed.

Dr. Early moved that the whole subject be laid on the table. Lost.

Dr. Flick and Dr. Roberts opposed the amendment proposed by Dr. Dulles.

Dr. Packard spoke for the amendment.

Dr. Bishop favored the amendment.

Dr. Woods, of Erie, wanted a list so that he could vote against every man in his district who voted against the bill.

Dr. Waugh moved that the amendment be laid upon the table. Carried.

Dr. Roberts' motion was then adopted.

Dr. McCormick introduced a resolution:

Resolved, That the Presidents of the different County Medical organizations entitled to representation in this Society shall constitute a committee which shall be known as the Legislative Committee. The President of the State Society shall call a meeting, at some convenient point, of this Committee, as soon as possible after the adjournment of this Society. At this meeting the Committee shall organize by the election of such officers as they may think proper and take such action as they may deem best to secure the passage of a medical law that will give protection to the people of this State against incompetent practitioners of medicine. The necessary expenses of the Committee to be paid by the State Society. Provided, that in the event that the President of any County Society neglects or refuses to serve, the Chairman of the Committee shall appoint some one to represent that county. Carried.

Dr. Samuel Ayers, of Pittsburgh, read the report of the Committee on the

Management of Pennsylvania Hospitals for the Insane,

in which he said that the Committee had not been able to make any full report because it could not have a meeting.

Dr. E. A. Wood offered as a substitute for the report the following:

Resolved, It is the sense of this meeting that the Medical Superintendents of our State insane asylums should be restricted exclusively to the treatment of the insane

inmates, and also that one or more female physicians should be appointed, whose duty, under the control of the Superintendent, shall be to have charge of the female insane patients, and we urge the Legislature to enact such laws as shall make the reform obligatory.

Dr. Schultz opposed the criticisms that superintendents have to oversee, personally, every detail of the management of hospitals for the insane, any more than a captain of a ship has to attend, personally, to the shovelling of coal into the furnaces of a steamship; and defined the real relation of superintendents to their inferior officers and to the trustees.

Dr. Jackson, Dr. McKennan and Dr. Bishop spoke to the motion.

Dr. Traill Green repudiated the idea that the Committee knows nothing of the subject.

Dr. Ayers read a paper prepared by himself in regard to the subject and which was not adopted as a report by the Committee because the attendance of the Committee did not justify them in offering a formal report. His statement recommended the appointment of women physicians for the female patients, the appointment of a consulting medical staff and the appointment of a purser to aid in managing the affairs of hospitals for the insane.

Dr. Curwen spoke against the resolution and defended hospital superintendents against the charges brought against them.

Dr. Gerhard also spoke.

Afternoon Session.

The Committee on Nominations reported nominees:

For President—Dr. A. Craig, Lancaster Co.

Vice-Presidents—Dr. T. H. Van Valzah, Mifflin; T. McKennan, Washington; W. S. Foster, Allegheny; S. D. Bell, Butler.

Treasurer—Geo. B. Dunmire, Philadelphia.

Permanent Secretary—W. B. Atkinson, Philadelphia.

Recording Secretary—Charles W. Dulles, Philadelphia.

Corresponding Secretary—Israel Cleaver, Berks.

Committee on Publication—Edward Jackson, Philadelphia; G. W. Guthrie, Lycoming; S. H. Gump, Bedford.

Censors—First District, J. W. Walk, Philadelphia.
Fourth District, A. M. Smith, Snyder.
Fifth District, John Montgomery, Franklin; I. C. Gable, York.
Sixth District, D. P. Miller, Huntingdon; H. M. Lichtz, Somerset.
Seventh District, J. S. Hackney, Fayette.
Ninth District, J. A. Ritchey, Venango; J. M. Cresswell, Clarion.
Tenth District, A. A. Woods, Erie.

For Judicial Council (as two years have passed since appointments were last made):

For 2 years, S. S. Schultz, Danville; J. H. Packard, Philadelphia; John Curwen, Warren.

For 3 years, A. M. Miller, Bird in Hand; W. T. Bishop, Harrisburg; Traill Green, Easton.

Delegates to American Medical Association—H. G. McCormick, Lycoming; S. Birdsall, Susquehanna; W. B. Lowman, Cambria; J. P. Connelly, Lycoming; G. G. Harmon, Huntingdon; J. Q. Robinson, Westmoreland; C. W. Coulter, Venango; M. M. Magoffin, Mercer; W. Ray Grayson, Washington; F. L. Marsh, Westmoreland; J. Y. Shearer, Berks; A. Harshberger, Mifflin; J. F. Summerville, Clarion; T. C. Rich, Lycoming; S. S. Good, Somerset; J. S. Hackney, Fayette; T. B. Hill, Greene; I. A. Armstrong, Armstrong; John B. Roberts, Philadelphia; W. B. Ulrich, Delaware; S. P. Bartleson, Delaware; D. K. Gotwald, York.

To International Medical Congress—J. L. A. Burrell, Lycoming; J. A. Ritchey, Venango; E. M. Corson, Montgomery; J. K. Weaver, Montgomery; A. M. Miller, Lancaster; J. K. Lineaweaver, Lancaster.

To State Society of New Jersey—E. V. Swing, Chester.

To State Society of Maryland—I. N. Snively, Franklin.

Time of meeting, the first Monday in June, 1891; the place, Reading, Pa.

On motion the report of the Nominating Committee was adopted, and the Berks

County Medical Society was authorized to appoint a Committee of Arrangements.

A telegram from the Pennsylvania Pharmaceutical Association was read by Dr. Atkinson, and thanks and congratulations were sent in return.

Dr. E. A. Wood moved to send congratulations to the Society of West Virginia, now in session.

Dr. E. A. Wood was nominated and elected to the Judicial Council to fill the vacancy caused by the resignation and removal to Ontario of Dr. J. R. Taylor, of Phillipsburg.

Dr. James Tyson read a paper on the

Management of Obstinate Dropsies,

recommending skimmed-milk diet for removal of dropsies, with spartein ¼ to ⅓ grain, t. d. and milk at regular intervals and in fixed doses.

Dr. Samuel Ayers, Pittsburgh, read a paper on

Trephining in Traumatic Insanity.

In it he described a number of cases in which he trephined and in which the results were very satisfactory; and he advocated the method as having very little danger and giving a good chance of improvement to the patient.

Dr. Murdoch described a case in which there was a remarkable recovery after loss of brain substance.

Dr. John B. Roberts read his

Address on Surgery,

in which he gave a careful account of the present view in regard to the relation of bacteria to practical surgery. He described the different forms of micro-organisms which influence surgery, and urged the absolute duty of surgeons to observe bacteriological cleanliness.

Dr. R. B. Mowry spoke upon the paper, and said it explained some of the difficulties presented in the discussion on the contagiousness of tuberculosis.

Dr. Traill Green read a paper on the

Chemistry of Cooking,

in which he spoke of the necessity of having correct knowledge in regard to the digestibility and nutritious properties of various articles of food; and described the chemical composition and mode of preparation of certain foods, animal and vegetable, and the effect of different forms of cooking.

Speaking of the frying-pan, he said that the grease with which it fills food makes this much harder to digest. He also objected to the use of lard instead of butter in cooking, and described the processes of raising dough and baking it.

Dr. G. W. Allyn spoke about beef teas and beef extracts, and said that most of them contained, Liebig's especially, only the stimulating part and not the nutritious part of the meat.

Dr. E. A. Wood paid a warm tribute to Dr. Traill Green for bringing a paper before the Society. He spoke of the fault of overdoing cooking and preferring the pleasing of the palate to the needs of the system; and cooking food so soft as to require no chewing. The effect of the use of so much soft food for children and liquid food is to produce narrow and weak jaws which will not hold thirty-two teeth, and poor teeth. He earnestly advocated the use of harder food to exercise and develop the jaws and teeth. He said "If I were dictator of this country, I would undertake to raise a race of men and women who would put to shame the ancient Greeks, who were like gods and goddesses; instead of such as in early life have their mouths filled with the products of the dentist's laboratory."

Dr. A. B. Brumbaugh recommended addition of salt to milk, and to boil eggs hard and grate them, adding a little milk.

Dr. J. H. Packard made some remarks on the

Value of Primary Anæsthesia from Ether.

Dr. John Aulde read a paper on

Arsenite of Copper,

in which he reported the results of his investigation of the therapeutic value of this drug. He began to use it two years ago. The mode of administration is in powder or in tablet triturates. It is useful in cholera morbus, colicky pains, cholera infantum, diarrhœa and dysentery, anemia, chlorosis. The latter was recommended by Dr. L. G. Broughton, of Reidsville, N. C. He gave an account of the findings of reports of 520 cases treated by correspondents.

Dr. Atkinson read the Report of the

Committee on Clinical Research,

which showed that the members of the Society have made an insufficient response to their request for co-operative study. Dr. Roberts resigned from the Committee.

Third Day, Thursday, June 12.

Morning Session.

Dr. Frances N. Baker, Delaware Co., made the

Address in Obstetrics.

Dr. J. Milton Duff, Pittsburgh, read a paper on

Rational Midwifery.

He protested against the methods of those ill-prepared and unfit to practice obstetrics. He advocated at least one preliminary examination—before full term—in every case of pregnancy. To show the great difference of methods on the part of different obstetricians, he cited the statistics of a number of men, some of whom in a limited number of cases had a relatively large proportion of craniotomies, still-births, adherent placenta, etc. He objected to the too free use of ergot and the forceps, and said that antisepsis without cleanliness is void.

He said the history of abortion is the history of civilization and that as the laws against abortion have multiplied so have the cases in which it was practiced; and not long ago a certain obstetrician advocated the prostitution of his art by practicing it scientifically. He said embryotomy and cephalotripsy, with a living child, ought to be abandoned for laparotomy. But laparotomy must not be deferred until after a woman is worn out and her soft parts lacerated and bruised by vain efforts to remove a fetus by the natural passages.

Dr. Geo. B. Dunmire, Philadelphia, read a paper on

The Use of Ergot in Labor,

in which he objected to the indiscriminate use of ergot and cited his own observations and the results of his examination of the Reports of the Board of Health of Philadelphia. These confirm his opinion that ergot is a remedy to be used with the exercise of the greatest discretion. He advocated no use of ergot before the third stage of labor, and the establishment of schools for the instruction of midwives.

Dr. Mordecai Price read a paper on

What Should be Required of an Abdominal Surgeon,

endorsing Dr. Duff's views as to preparation for the work of an obstetrician, and urged the importance of careful study and observation under the best masters before a man shall undertake to do abdominal surgery.

Dr. Ulrich called attention to the abuse of privilege in members carrying off papers from the room instead of delivering them to the Secretaries, and said he saw in a Pittsburgh newspaper this morning a paper (published in full apparently) read before this Society yesterday, with a picture of the author.

Dr. H. H. Whitcomb, Norristown, asked the opinion of the Society as to the use of the oil of cinnamon. He said a practitioner in Norristown said he was in the habit of giving five drops of extract of ergot and one drop of oil of cinnamon before labor and he never had post-partum hemorrhage.

Dr. Longaker said he had no use for ergot whatever, and endorsed Dr. Dunmire's designation of it as "the deadly spur."

Dr. E. E. Montgomery recommended the use of bromide of ethyl as an anæsthetic in labor. It is rapid in action, safe, and its effects pass off soon, leaving no unpleasant results. He once advocated the use of electricity in the early stages of extra-uterine pregnancy; but now he has changed his mind and gave good reason for this change, from cases coming under his own observation or occurring in the practice of others. He endorsed Dr. Duff's reprobation of embryotomy when the fetus is living, and said the obstetrician should be the guardian of the helpless child. The mortality of Cæsarean section he attributed to delay in practicing it until after various other measures for delivery had been tried.

Dr. Traill Green spoke of the practice of abortion and characterized it as murder. There is a man in Easton, who is a Christian, who believes that "a doctor ought always to help young ladies out in this trouble." Dr. Green tells people that it is murder and that people who commit murder go to hell. People say it is diabolical, but he had never heard of the devil performing this operation. He described a case of conviction of abortion and the attempts to have the abortionist pardoned and his efforts to prevent such an outrage. He said: "I devote myself henceforth to catching these rascals."

Dr. C. R. Early spoke of a case of abortion where conviction was followed by a prompt pardon.

Dr. Mordecai Price suggested that physicians be careful not to conclude that a criminal abortion has been performed by a man.

Dr. Buchanan endorsed Dr. Price as to

abdominal surgery in general; but thought he went too far in saying that no one should practice it who has not all the qualifications he described; and that this restriction would have retarded the advance of abdominal surgery. Men, good surgeons in general and well prepared in anatomical knowledge and acquaintance with the literature of the subject, are justified in operating themselves, and need not send their patients away or let them die unrelieved.

Dr. Edward Jackson, Philadelphia, read a paper on

Suppurating Ulcer of the Cornea,

for which he recommended thorough scraping the cornea with the spud.

Dr. G. H. Cline, Jersey Shore, described a form of glasses.

Dr. Dulles introduced the following resolution:

Resolved, That the President appoint a committee of three members who shall secure the incorporation of the Medical Society of the State of Pennsylvania, naming as trustees for the first year the present members of the Judicial Council.

This was adopted by a unanimous vote.

Dr. Wm. C. Bane, Pittsburgh, read an account of a case of

Sarcoma of the Choroid.

Afternoon Session.

The report of the Committee to Revise the Constitution was presented and was ordered to be printed.

Dr. Alice Bennett, Norristown, read the

Address in Mental Disorder,

in which a number of cases of insanity of various forms were described and explained. She spoke of the possible similarity of nature between chorea and convulsions and dwelt at some length upon the relation of diseases of the kidney to insanity.

Dr. E. A. Wood spoke of a form of insanity due, he thinks, to disease of the liver, which is mistaken for disease of the kidneys, and in which what is thought to be albumin is really a glycogen.

Dr. G. M. Shilto, Allegheny, read a paper on

The Application of Dry Heat by Steam,

and described and showed an apparatus which he has devised for this purpose.

Dr. A. B. Brumbaugh, Huntingdon, read a paper on

La Grippe or Epidemic Influenza,

in which he described his own experience in the recent epidemic. He found the disease characterized by disturbances of the gastric rather than of the respiratory tract. His treatment was principally directed to the latter, and his results were very satisfactory. He did not regard the disease as contagious.

Report of the Committee to Confer with the State Committee on Lunacy.

Dr. Mordecai Price moved that the Committee on Publication be authorized to omit from the volume of Transactions the Address in Laryngology, by Dr. Wm. H. Daly, which was published in a daily paper of Pittsburgh this morning, together with his portrait.

After some discussion, a motion by Dr. Shaw to lay the original motion on the table was lost, on a division, ayes 19, noes 25. The original motion was then carried, on a division, ayes 33, noes 17.

Fourth Day, Friday, June 13.

The President appointed to deliver the addresses at next meeting: In Medicine, Dr. J. Chris. Lange, Pittsburgh; in Surgery, Dr. O. H. Allis, Philadelphia; in Obstetrics, Dr. John Milton Duff, Pittsburgh; in Hygiene, Dr. A. B. Brumbaugh, Huntingdon; in Mental Disorders, Dr. Samuel Ayers, Pittsburgh; in Ophthalmology, Dr. J. A. Lippincott, Pittsburgh.

Dr. Murdoch made a speech on retiring, and introduced the President-elect, Dr. Alex. Craig, of Columbia. Dr. Craig assumed his duties and thanked the Society for the honor conferred upon him.

On motion of Dr. Bishop the thanks of the Society were tendered to President Murdoch, to the Allegheny County Society, and to the citizens and ladies of Pittsburgh.

Dr. Murdoch moved that the Publication Committee be instructed to have a memorial of Dr. Henry H. Smith in the next volume of Transactions with a steel plate or engraving. The motion was carried.

The Society adjourned to meet at Reading on the first Tuesday of June, 1891.

PERISCOPE.

Fracture of the Anterior Superior Spinous Process of the Ilium from Muscular Action.

In the *Boston Medical and Surgical Journal*, March 6, 1890, Dr. N. Nickerson, of Meriden, Conn., reports a curious case of a very rare form of fracture.

A boy, aged seventeen, while running a foot-race of one hundred yards, was suddenly brought to a stop by feeling something give way in his hip, with a sensation of bones grating together. He found that he could not take another step, and was carried home where Dr. Nickerson saw him within an hour after the accident. On examination he found distinct crepitus, with motion of fragment, on pressure upon the anterior superior spinous process which elicited considerable evidence of pain.

The leg was placed in a flexed position, resting on a fracture apparatus, but without bandage or other appliance to keep the parts in apposition, and the point of injury kept bathed in an evaporating lotion for several days. At the end of two weeks the boy began to walk cautiously by the aid of crutches, and in three weeks dispensed with them altogether, though using care in going up and down stairs or over rough ground.

The diagnosis in this case was confirmed by Drs. E. T. Bradstreet and E. W. Smith, who saw the case with Dr. Nickerson.

The following extracts may be of value to those physicians who have not access to large medical libraries, and contain all that Dr. Nickerson has been able to find bearing on this fracture.

In the New York *Medical Journal*, Volume XII, page 184, and the Canada *Medical Journal*, Volume VII, page 97, Drs. S. Joy and J. W. McWhinnie report this case: Augustus S., age seventeen, a medical student, was engaged in a foot-race where a certain distance had to be run, then to turn and run back. In the exertion of turning he felt something snap in his right hip, and walked a few steps and fell. On examination, distinct motion and crepitus could be felt, by the pressure over the process, also by placing the thumb over the origin of the sartorius and rotating the thigh.

The patient was placed in bed, with the thigh flexed and the shoulder raised, a bandage being applied to aid in steadying the fracture. This position and adduction of the leg were maintained by bands attached to the posts of the bed. In two weeks the patient made a good recovery without displacement. In commenting on this case, the doctors make the following observations: "In looking up the literature of fractures of the anterior superior spinous process of the ilium, we read of their occurrence from direct violence, but not one case is recorded as having taken place from muscular action."

In the *British Medical Journal*, 1872, page 549, this case is reported by Dr. George J. Seeley: A young man, age seventeen, of good muscular development, whilst running vigorously in a foot-ball match, was suddenly brought to a standstill by a snap in his side, followed by a feeling of "coming in two." Being quite unable to take another step he was carried to the house, and, on my examining him about an hour afterwards, I found considerable tenderness along the upper head of the rectus femoris, and a piece of bone, as large as the top of a finger, detached from the ilium; crepitation was very distinct.

In the same journal for 1872, page 513, Dr. W. E. Hyde reports another case, as follows: A young man eighteen years of age, whilst running over some uneven ground suddenly felt as if a stone had been thrown at him, striking him on the hip, and then felt that he could not move again. He was carried home, and upon my arrival an hour afterwards I found that he was unable to draw his leg forwards, and upon examination I found one head of the rectus femoris torn from its attachment to the ilium with a piece of the bone, about the size of a half damson, perfectly movable, so much so that distinct crepitus could be felt by moving the surfaces of the fractured parts together. I flexed the thigh and applied a pad with a figure-of-eight bandage round the pelvis and thigh. At the end of two weeks union had taken place, with formation of callus, and in another week he could walk about with some difficulty.

Dr. Hamilton, in his classical *Treatise on Fractures*, etc., gives this as the only case coming under his observation. William Alexander, aged seventy, on the 5th of September, 1869, after riding in a railroad car about half an hour, arose to leave his seat when he felt "something wrong" in his right groin, and found himself unable to walk without great pain. He was admitted to Bellevue Hospital on the same day, and

I found a fracture involving about three inches of the ilium, including the anterior superior spinous process. It was inclined to fall outwards, but was easily replaced, with a distinct crepitus.

The following remarks are taken from the *Treatise on Fractures*, by Lewis A. Stimson, M. D., as the last word on the subject: "Dr. Hamilton has reported a case of fracture of the anterior superior spinous process of the ilium by muscular action, and the same agency appears not improbable in other fractures of the same part. Riedinger asserts the same cause in many fractures of the crest. Considering the strength of the muscles attached to the ilium, and the occasional correspondence of the fragments to the insertion of the muscles, the theory does not seem unreasonable."

Albuminuria.

In a digest of walking cases of albuminuria, by Dr. James F. Goodhart, in the *Medical Press and Circular*, Feb. 12, 1890, the author stated that his observations were derived from an examination of 272 cases of albuminuria which had come under his notice during the last ten years. Dr. Goodhart called special attention to a form of congestive albuminuria in which the patient complains of a certain amount of ill-health, whilst on inquiry it is found that he eats and drinks too much, takes no exercise and probably has gouty antecedents. In such cases the urine is of high specific gravity, and contains only a small amount of albumin. The treatment consists in the periodical administration of a purge, and in making the patient live according to the ordinary laws of health. When these can be followed the albumin soon disappears from the urine. These cases are clearly not due to nephritis, and it is in describing the pathology of such an affection that the term "congestive" is of service. The temporary presence of albumin in the urine can also be sometimes explained by the fact that in females the urine has become mixed with leucorrhœal discharge, whilst in the male the seminal and prostatic secretions may produce a similar result.

Dr. Goodhart also maintained that intermittent albuminuria often occurs in highly neurotic persons, and to prove this point he quoted the details of several cases which had come under his notice. In such instances the occurrence of albuminuria may, perhaps, be explained by assuming that there has been oxaluria or some temporary disturbance of the digestive functions. In other cases where albumin appears in the urine after scarlatina, and is therefore presumably due to nephritis, the patient remains in good health. In such instances Dr. Goodhart thinks that the phenomenon is to be explained by supposing that each organ in most individuals has a margin of working power which can be temporarily encroached upon without bad result. Acute nephritis may run its course without any dropsy, and it is then very likely to be overlooked unless an examination be made of the urine. Dr. Goodhart related two such cases occurring in children who were first cousins to each other; in both instances the skin was remarkably dry and shrivelled. In one of these cases a *post-mortem* examination was obtained, when it was found that the kidneys were small, their capsules adherent, their surfaces pale and speckled, the cortex much diminished in amount, whilst microscopically the malpighian tufts were seen to be undergoing hyaline degeneration. On the other hand Dr. Goodhart has seen cases of chronic parenchymatous nephritis associated with dropsy lasting for some months, the patients recovering completely even when their cases had appeared almost hopeless. Albuminuria may alternate with the elimination of uric acid, or of sugar of the kidneys. In such cases it seems as if there was a sudden unlocking of abnormal metabolic process, but it is, perhaps, more correct to say that there are oscillations in the pathological processes and formations just as there are in Nature, or in the normal body heat. In cases of albuminuria Dr. Goodhart lays down the following as a good rule of practice: "If a case presents itself for examination, and albumin is found in the urine, it is a case for further examination; if it be in a young person, and the examination be conducted upon the urine of the early morning, the albumin will probably have disappeared at the next examination or within a very short time, and it is a condition of no importance. If the albumin is in any quantity, and its presence is persistent, or re-appearance frequent, it must be regarded, to use Dr. Gairdner's apt expression, as a danger signal to be watched, and, personally, I believe that some of the cases at any rate are due to patches of inflammation irregularly distributed in the kidneys."

Dr. Goodhart believes nitric acid to be the best form of test for albumin occurring in the urine, he has of late years discarded picric acid on account of the frequency with which this reagent causes a difficulty when quinine has been administered. Picric acid, however, undoubtedly makes the greatest show when there is only a trace of albumin.

Pulque in Hydrophobia.

In a Peruvian journal, *La Crónica Médica*, Dr. Pablo Patron relates a case of a boy who had been bitten by a rabid dog. Although the wounds were antiseptically treated, the boy began to show signs of hydrophobia. One day he escaped into the fields, where he gathered leaves of the American aloe (*Agave americana*) and sucked them. Subsequently the boy recovered from the disease and the agave gets credit for the cure. *Agave americana* not being readily obtainable in this country, any one under the painful necessity of requiring treatment of this kind might try pulque, which is the juice of the *Agave americana* slightly fermented. Pulque is readily obtainable.—*Chemist and Druggist*, April 26, 1890.

Gum Cahori.

Gum cahori is the resin of a tree called dammara or agahi, belonging to the coniferæ, and indigenous to New Zealand and New Caledonia. The gum is extensively employed in the manufacture of varnish. Two forms are recognized: the fossil and the recent. Gum cahori is soluble in alcohol at a temperature of 90° C., and also soluble in ether. By distillation an essence is obtained which has an odor of turpentine. A solution of the resin in its essence may be employed in the preparation of histological specimens in place of Canada balsam.

M. Fornet, in the *Mecredi Médical*, April 9, 1890, states that the alcoholic solution of the gum may be used advantageously as a substitute for collodion as a protective dressing for superficial wounds. It is of a syrupy consistency and has an agreeable odor. It may also be used in place of collodion in cutaneous affections. Finally, when given internally it has been observed to act beneficially in cases of catarrh of the bladder.

Eczema of the Face in Infants.

Besnier, in the *Annal. de Obst. Gin., y Ped.*, February, 1889, says that eczema of the head presents three forms during infancy. The first occurs in lymphatic and scrofulo-tuberculous subjects, its principal characteristics being moderate pruritus, infarctions of the lymphatic ganglia of the nose and mouth, which may result in tuberculous lesions with abundant secretion. Often there is also phlyctenular keratitis. The second form occurs during dentition. In this form the itching is intense, the head being covered with the eruption. The gums may also be sensitive, and salivation be decided. To soothe the irritation of the gums frequent applications of the following formulæ are recommended:

℞ Glycerini
Aq. destil. . . . . āā 80 parts
Potass. brom. . . . . 7 "
Cocain. mur. . . . . 7 "

If the sleep is disturbed, give four teaspoonfuls, with intervals of an hour each, of the following:

℞ Potass. brom. . . . . 7 parts
Mucil. acaciæ . . . . . 400 "

Topically the following may be used:

℞ Zinci oxidi . . . . . 24 parts
Vaselini . . . . . 68 "

In the third variety there is no itching. The trouble is principally in the skin of the scalp, and is characterized by abundant desquamation of the skin. It may extend to the body and limbs. The hair should be cut off, and the skin of the scalp washed with soap and water, to which a little milk may be added. Then an application may be made of the following:

℞ Resorcin . . . . . 7 parts
Zinci oxid. . . . . 60 "
Vaselini . . . . . 900 "

Instead of the resorcin three or fou grammes of sulphur, or twelve to twenty-four grammes of ichthyol may be used.

In the scrofulo-tuberculous form the affected portions should be bathed twice daily with a mild solution of Van Swieten's liquor, after which an ointment should be applied containing one part of calomel and thirty of a suitable excipient.—*Archives of Pediatrics*, April, 1890.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

MISMANAGEMENT OF THE PHYSICIANS' REGISTRATION ACT.

A recent investigation by the MEDICAL AND SURGICAL REPORTER of the registration of physicians as conducted in the Prothonotary's office in Philadelphia, has demonstrated several things which deserve some comment. In the first place, the law governing the registration of physicians is so defective in its language that it is quite capable of interpretations which would seem to make legal the registration of persons having no claim whatever to be considered physicians.

The intention of the law, in permitting the registration of persons who had been in practice for ten years when it was passed, seems clear enough, but its wording is so stupid that it is held by the Prothonotary that persons who assert that they were in practice in Pennsylvania from 1871 to 1881, can still be registered as physicians under the "Ten Years' Practice Act," passed in 1881. In doing this the Prothonotary makes no account of the intervening years in which such persons were out of practice or were practicing illegally.

Again, the law provides that any person representing that he has lost his diploma by fire or otherwise may register as a physician, upon making an affidavit to that effect, stating the "names of the professors whose lectures he or she attended and the branches of study upon which each professor lectured. Not a word is said requiring that the studies shall have been in a medical school of any sort; and, so far as we can see, one might register who could affirm that he had studied in a high school or what is called a commercial college.

Again, it is held by the Prothonotary that any person holding a diploma from the "Philadelphia University of Medicine and Surgery," the "American Eclectic College" or any of the other fraudulent institutions which ever existed in Pennsylvania, though now broken up and though their promoters are in prison may still register as a physician, provided that his fraudulent diploma is dated earlier than the time when the courts declared these diploma mills to be illegal or their charters were forfeited.

The records at the Prothonotary's office show that these defects of the law have been taken great advantage of. It is curious and suggestive to note that physicians who have been convicted of malpractice, misdemeanor and abortion within the past ten years have almost, without exception, been graduates of Paine's or Buchanan's fraudulent and disbanded schools, or else have registered under the "Ten Year Act." It is equally noteworthy that these names are still on the register and their license to practice has not been forfeited.

In regard to the administration of the registration law by the Prothonotary, it is found that he has turned the whole over

very largely to his clerk and that the facilities afforded the latter for keeping the registration papers in order are very poor. This may partly account for the fact that the affidavits, certificates and copies of diplomas are not properly filed or preserved, but are in confusion and disorder; rendering a search for any one paper very difficult. The papers that have been numbered are not filed in proper numerical order, while a large number of recent papers are not numbered at all. Some of the papers cannot be found at all, and others, which could not be found by our representative, after a most careful search, were subsequently discovered by the clerk.

In the registration books, a large number of the affidavits have not been signed by the physicians, and in many other cases the clerk has written their names to the affidavits *himself!* He gives, as an excuse for this remarkable performance, the statement that the physicians got away from the office before he could get their signatures, or that he must have been very busy at these times. When it is considered that these signatures are appended to sworn statements made by the registering physicians, the significance of what we have discovered in regard to them will be apparent.

In investigating the facts in connection with certain individuals about whom the profession would like to know something, we have found what follows.

The affidavit of Henry W. Lobb, an advertising physician (practicing under the ten years' practice clause), could not be found, although the register contains the statement that one is on file; the only paper referring to him is a letter from Dr. "Bartholomew," stating that Dr. Lobb had studied medicine under him for three years. A. J. Kimball is registered as a graduate of the Bennett Eclectic College, of Chicago. A copy of his diploma is filed but is not endorsed by any Pennsylvania medical school. Kate Koenig and J. A. Heintzelman are registered under the "Ten Years' Act," but there is no record in regard to when they practiced and their affidavits could not be found. Harriet Hinkle and Sarah A. Spare are registered under the "Ten Years' Act" as "Cancer Specialists." Eliz. Wiegand is registered under the "Ten Years' Act," but she has signed the register *E. Wild;* her affidavit cannot be found. Eliza Morong, who is registered under the "Ten Years' Act," apparently could not write, for she made her "mark" both to the register and to the affidavit.

In all sixty-five persons who have no diplomas are registered as physicians.

That the cases alluded to represent only a small fraction of the questionable registrations in Philadelphia, we have no doubt; but the cases cited will suffice to show how imperfect is the registration law in this State, and how loosely it is administered in this city. It was supposed, when the Prothonotary appointed as his clerk a physician, that the latter would do whatever he legally could to prevent the weak features of the law from working injury to the community. But it seems that to the natural defects of the law have been added carelessness in the Prothonotary's office—if not worse. The individual who is primarily responsible to the people for this is the Prothonotary, and it may be necessary for the Reporter and the Philadelphia County Medical Society—which also is engaged in investigating the subject—to call attention to what appear to be the reasons why the law has been administered as it has been in certain cases.

For the present we content ourselves with calling attention to the matter, so that our brethren throughout the State may understand that in this city something is being done to correct a state of affairs which we know exists in other parts of the Commonwealth as well as here, and with the hope that what we have done may encourage others to investigate and report the defects of execution of the registration law in their own counties.

SURGICAL TREATMENT OF ABSCESS OF THE LIVER.

A casual glance over the most prominent text-books of surgery is sufficient to show that the treatment of hepatic abscess is but briefly dealt with. Aspiration, tapping by trocar, and free incision are recommended, as the needs of the case may indicate. The treatment by laparotomy, either by one or by two stages, as endorsed by Lawson Tait, Pye Smith and Taylor, has also found favor. But at best recovery after any of these methods is slow, and fatal issues are not infrequent. It is noteworthy that the after-treatment of abscess of the liver is but sparingly dealt with in the majority of the books, and a great deal of the surgeon's knowledge is taken for granted.

Mr. Vaughan Harley, in an address before the British Medical Association, reported in the *Medical Press and Circular*, April 30, 1890, described a rapid mode of cure for abscess of the liver, which both in his hands, and in the hands of others has yielded most gratifying results. Before describing Mr. Harley's operative procedure, in order that the *rationale* of the process may be readily understood by those who have given no special attention to hepatic diseases, the following particulars are subjoined, from Mr. Harley's paper.

1. Inflammations of the liver end much more frequently in purulent formations, in hot than in cold countries. 2. Men are far more liable than women to liver suppurations. 3. Although an abscess of the liver may occur at any period of life, it is much more common between the ages of twenty and fifty years than at any other. 4. Suppurations of the hepatic tissues are most frequently met with in strumous subjects; and the most unsatisfactory cases of all to treat are those in which a syphilitic taint is superadded to a constitutional struma. 5. The most noted predisposing causes to liver abscess are struma and alcohol even when alcohol is indulged in within what is usually regarded as the limits of moderation. 6. The commonest of all the exciting causes is a sudden chill. 7. All abscesses of the liver tend to evacuate themselves by burrowing their way to the surface of the organ, and seeking an outlet for their contents either directly through the abdominal walls, or indirectly through the pulmonary or digestive systems. 8. It is futile to evacuate a liver abscess either by knife or trocar so long as a free opening is not left to give escape to the subsequently formed pus. 9. When an accumulation of pus has taken place in the liver it not only tends to do serious mischief by causing disintegration of the hepatic tissues, but also, from its becoming putrid, to kill the patient by blood-poisoning. This likewise occasionally happens when hydatids of the liver suppurate. 10. Cancerous and tuberculous deposits in the liver, by disintegration, sometimes lead to the formation of purulent formations. 11. As soon as the existence of purulent matter in the liver is detected it should be evacuated, and the more promptly it is done, the better will be the patient's chances of recovery.

The presence of pus being suspected, its exact situation should be searched for in the following manner. A fine exploring trocar eight inches long is to be passed into the liver obliquely from right to left, or *vice versa*, according to the site the abscess is thought to occupy. Then the instrument should be slowly withdrawn so as to allow sufficient time for a drop of pus to appear at its orifice. If pus be found its situation and depth in the organ should be carefully noted. If blood instead of pus flows, the bleeding ought to be encouraged. For, in cases of suspected hepatic abscess there is always more or less congestion, and marked benefit is likely to arise from a free hepatic phlebotomy.

The presence of pus having been substantiated, before withdrawing the exploring canula as much as possible of the purulent matter should be allowed to flow from it. Immediately on its ceasing to flow through the narrow tube, the surgeon should intro-

duce, in exactly the same direction and to precisely the same depth, one of the diameter of a No. 8 or No. 10 catheter English scale, and through it empty the abscess completely by means of an aspirator. When empty the cavity should be washed out with tepid water containing ten grains of boric acid to the fluid ounce, and the washing should be continued until the liquid returns clear and odorless. Then as large a silk elastic catheter as will pass through the canula into the abscess cavity should be inserted, and on withdrawing the canula the extruding end of the catheter should be cut off to within one and a half inches of the opening in the abdominal wall, and securely fastened there. This done, the whole should be covered with a hot soft linseed poultice.

The abscess cavity should be washed out with boric acid solution night and morning, and poultices should be constantly applied until the purulent discharge almost entirely ceases. If, however, as occasionally happens, the cavity refills, another opening should be made at a short distance from the first, and a second drainage-tube should be introduced. This counter-opening, by facilitating the washing-out process, greatly hastens the cure.

The advantages of this mode of treatment are well illustrated by the report of two most unfavorable cases, in which it was employed with complete and speedy success. The first case was that of a patient who, before the operation, nearly died with blood-poisoning, due to absorption into the circulation of the poisonous products of putrid pus. This patient was exceedingly weak, both in body and in mind. The liver dulness extended from the nipple to the umbilicus. At the time of the operation his pulse was 108, and his temperature 102° F. Sixteen fluid ounces of pus were evacuated, and the prescribed treatment was rigidly adhered to. The next day the pulse was 99 and the temperature 100°; and twelve days after the operation the patient was able to return home. The second case was one of multiple abscess occurring in the greatly enlarged liver of a strumous patient. The liver dulness extended from the nipple to two inches below the umbilicus. The day of the operation the patient's temperature was 103° F., and his pulse 120. Three days after the first abscess had been evacuated, a second one was discovered and treated in the same way. Recovery was rapid, and in three weeks all discharge from the wound had ceased.

The advantages of treating liver abscesses in the manner described may be briefly summed up in the following sentences. First, by the employment of boric acid we have not only the assistance of a thoroughly safe antiseptic agent, but the great advantage which accrues from the use of one free from the objection of coagulating the albuminoids in the pus, and thereby inducing a fouling of the instruments, such as is unfortunately the case with carbolic acid and most other antiseptic preparations. Second, the daily washing out of the abscess cavity with boric acid solution not only expedites the healing process, by keeping it clean, but has the further advantage of rendering it quite unnecessary to take any precautions against the intrusion of air into the cavity, no matter how large it is. Third, the washing out of the cavity with boric solution, from its enabling us to get rid of all the purulent matter, thick as well as thin, does away entirely with the necessity of making a large opening either through the abdominal walls or into the liver tissues with a knife or other instrument—a point of no slight importance, seeing that it is a well-recognized surgical axiom that the smaller the breach of continuity in any animal tissue, no matter whether it has been made accidentally or intentionally, the quicker proportionally is the healing process.

Mr. Hawley's method has also another point of value, namely, its simplicity. The procedure described is one which is easily understood and as easily carried out; and, should it prove as successful in others' hands as it has in those of Mr. Hawley and his

colleagues it will surely throw additional light and hope on the treatment of hepatic abscess.

AN ALLEGED ABORTIONIST.

The readers of this journal will be interested to know that we have followed up the case of Dr. Fackenthal, of Easton, whose methods were exposed in the REPORTER, May 31, and that in consequence of testimony furnished to the grand jury of that city a true bill has been found against him, and he has been placed under bail for trial. The date of his trial is set for September, and we shall inform our readers of its result.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

THE NEUROSES OF THE GENITO-URINARY SYSTEM IN THE MALE, WITH STERILITY AND IMPOTENCE. By R. ULTZMANN, Professor of Genito-Urinary Diseases in the University of Vienna. Translated by Gardner W. Allen, M. D., Surgeon in the Genito-Urinary Department, Boston Dispensary. Small 8vo, pp. 160. Philadelphia: F. A. Davis, 1889. Price, $1.00.

We are glad to welcome this translation of Ultzmann's two monographs, "Ueber die Neuropathien (Neurosen) des männlichen Harn- und Geschlechtsapparates," and "Ueber Potentia generandi und Potentia coëundi," especially as we understand that it has been made with the author's permission. After speaking of the urine and the changes produced in it by nervous influences, Ultzmann divides the neuroses of the urinary and sexual organs into three groups, according as they affect sensation, motion and secretion. Under neuroses of sensation are included hyperæsthesia of the urethra, the testicle, and the spermatic cord, and anæsthesia of these organs. *Impotentia coeundi* he defines as the impossibility of consummating the normal act of coition. The explanation of this condition, he says, is to be sought either in an organic change, a malformation, a defect in the penis, or, the penis being healthy and normally formed, in the inability to have a lasting and powerful erection. In the first case we have to do with an organic, in the second with a nervous or psychical impotence. The prognosis in the latter, he says, is usually favorable. Comforting advice and the assurance of complete cure should be given, but local treatment is declared to be the most effectual. Ultzmann prefers to use weak constant electrical currents in the following manner: The copper pole is placed over the lumbar vertebræ, and with the zinc pole the perineum, spermatic cords and penis are successively stroked. Duration of daily sitting two to three minutes; duration of treatment, six to ten weeks. In obstinate cases he employs the Faradic current and inserts a metallic staff into the rectum and applies the other pole successively over the bulb of the urethra, and right and left over the ascending rami of the pubes.

The motor neuroses of the urinary system include the spasmodic and paretic conditions of the bladder, while those of the sexual system include pollutions (nocturnal emissions) and spermatorrhœa. The author explains the distinction between these terms: Pollution is a copious evacuation of semen which takes place during sleep, generally at night, with voluptuous sensations and erect penis. Spermatorrhœa is a slight, dribbling and sometimes a continual flow of semen, without erection of the penis and without especially pleasurable sensation. Both forms may exist at times in the same patient. In the treatment of spermatorrhœa the author agrees in essential points with Gross in employing, in appropriate cases, bromide of potash, large metallic sounds, nitrate of silver injections to the prostatic portion of the urethra, and electrical stimulation.

The secreting neuroses have to do with the urine, the semen, and the secretion of the prostate. They are practically inseparable from the first two.

In the second monograph, on Sterility and Impotence, Ultzmann declares that ability on the part of man to generate depends solely upon the procreative power of the semen, while ability to copulate is often found unimpaired in cases in which the semen is absolutely sterile. The pathological changes in the semen are described as aspermia (absence of semen); polyspermia; and oligospermia (small amount of semen). The various abnormalities in color are also described. Azoöspermia is the name given to complete absence of spermatozoa.

The treatment of male sterility, the author says, is rarely accompanied with favorable results; it consists essentially in what is appropriate for spermatorrhœa.

The author is to be congratulated on having written in a scientific spirit upon a class of disorders which requires rare tact and a great amount of skill to manage successfully. We heartily recommend the book, and are especially glad that an excellent translation has made it accessible to a large class of readers.

NOTES AND COMMENTS.

Ouabain in Whooping-Cough.

Ouabaïn is an alkaloid with the formula $C_{30}H_{46}O_{12}$, and is obtained by crystallization from a watery extract of the roots of the ouabaïo, a plant nearly related to the *Carissa schimperi*. The juice of the ouabaïo plant is used as an arrow poison by the Somalis in East Africa.

Ouabaïn, its active principle, occurs in the form of rectangular crystals, which are white, transparent, colorless, and to a very slight degree bitter to the taste. It dissolves with difficulty in cold water, but much more readily in hot; it is altogether insoluble in chloroform or ether, and but to a slight extent in absolute alcohol. Its best solvent appears to be partly concentrated alcohol, and this solubility is increased by heat.

Professor Gley and M. Arnaud, both of

Paris, first studied the physiological effects of ouabaïn in frogs, rabbits and dogs, and they found that in a frog $\frac{1}{260}$ grain caused death by arresting the heart's action. In a dog, $\frac{1}{975}$ grain produced marked slowing of the respirations, without much cardiac disturbance; $\frac{1}{260}$ grain first stimulated, and then slowed respiration, until it ceased completely. Subcutaneously the drug was found to act much more powerfully than when given by the stomach; and $\frac{1}{65}$ grain, introduced into the blood through a scratch or otherwise, is said to be fatal to man.

Dr. Percy Wilde was the first to suggest the use of ouabaïo in asthma and whooping-cough, but it remained for Mr. William Gemmell to first test its value in this disease. His observations, which are reported in the *British Medical Journal*, April 26, 1890, are briefly as follows:

In this instance its use has been limited to cases of whooping-cough. Very small doses were employed at the outset; $\frac{1}{5200}$ grain (or half the lethal dose for a frog) was considered sufficient to start with, but this was quickly found to have little or no effect in controlling the disease. Accordingly the strength of the dose was increased from time to time until it was found that the standard dose for, say a child of 5 years, was $\frac{1}{1000}$ grain in solution every three hours.

Forty-nine cases of whooping-cough have been treated with ouabaïn. Of these, 25 have been dismissed well, 4 died, and the remainder are still under observation. Of the 4 fatal cases, 1 died from diphtheria, 1 from tubercular meningitis, 1 from acute capillary bronchitis, and the fourth from gradual and progressive emaciation. None of the fatal cases were under treatment with ouabaïn for a longer period than 10 days—one of them only for 4—and in all of them ouabaïn had been stopped at least a week before death took place. In none of the fatal cases were there any symptoms which might have been interpreted as indicative of ouabaïn poisoning. It is on the observations mentioned that the following general conclusions are based.

1. Ouabaïn is of marked benefit during all stages of whooping-cough, and, if carefully used, produces gratifying results. In the first stage it cuts short the attack; in the second, it reduces the violence and frequency of the cough, and diminishes the number of whoops, and in the third it hastens convalescence in a remarkable manner.

2. Ouabaïn is a drug the effect of which does not appear to be cumulative; its administration can be stopped suddenly without any ill effect beyond an exacerbation of the whooping-cough; it can be as suddenly resumed.

3. Ouabaïn should be given, at first at any rate, in doses not larger than $\frac{1}{1000}$ grain every three hours ($\frac{1}{125}$ grain daily).

4. For children under one year of age the dose should not exceed $\frac{1}{2000}$ grain every three hours.

5. In children of from six to twelve years of age, if the cough be very violent, and the whoops are numerous, $\frac{1}{500}$ grain may be given in each dose, but the action of the drug must be carefully watched.

6. Ouabaïn may be given alone, dissolved in water, or in combination with bromide of potassium, or chloral hydrate. The simplest way is to dissolve one grain of ouabaïn in distilled water, so that each minim of the solution shall be equal to $\frac{1}{1000}$ grain ouabaïn, as: ℞. Sol. ouabaïn, ♏ xlviii; syr. aurantii, f℥iv; aq. ad. f℥vi. M. Sig. A teaspoonful every three hours.

7. Under the administration of ouabaïn it is found that the temperature, pulse and respiration are, in uncomplicated cases, slightly below normal. When the drug is pushed the respiration becomes very slow; in one patient, aged four, it was often as low as sixteen per minute. It is from this side that danger is to be expected. An occasional irregularity of the pulse has been noted, and this always occurred in the evening.

8. Ouabaïn seems to promote the action of the skin. Within a few days—always less than seven, and usually three—of beginning treatment patients are noticed to be perspiring freely, and this is observed to continue so long as the drug is being given. The patient ceases to perspire so freely shortly after the drug is stopped.

9. The movement of the bowels is regular; the average number of motions daily is 1⅓. In no single instance was there any of that diarrhœa which is usually so troublesome a feature in whooping-cough.

10. The total amount of urine passed is slightly increased. The amount in each case of course varies with the age of the patient. The average daily amount over the whole 49 cases was 14½ ounces. The average age of each patient was 4 years 5 months.

It may be noted that in two of the cases under treatment sugar was undoubtedly

present in the urine on admission. This began to diminish in quantity, in one instance within three, and in the other within five days, after treatment was commenced; and in the first case on the eighteenth, and in the second on the nineteenth day of treatment the urine was noted as being free from the slightest trace of sugar. It remained so during the remainder of residence in hospital.

11. Professor Gley points out that four drops of a solution of 1 in 1,000 produce in a rabbit marked anæsthesia of the cornea, which anæsthesia lasts for about two hours. Mr. Gemmell failed to find this anæsthetic effect produced in any of his patients, although repeated experiments with a solution of the same strength have been made in nearly every case.

12. The appetite improves. This effect is striking, and has been noted in all the patients without exception.

13. The general physical condition improves considerably.

14. The sleep is sound.

Suffocation as a Cause of Sudden Death.

At the meeting of the New York Clinical Society, held Nov. 22, and reported in the *New York Medical Journal*, Feb. 22, 1890, Dr. R. Abbe narrated a personal experience in which he had undergone, to the point of insensibility, all the painful phenomena attending the accidental lodgment of a foreign body in the upper air-passages. He had also noticed that for a month afterwards his larynx was so sensitive and the muscles of the throat were so disturbed that the latter were apt to play him false and cause choking. He recollected a report of the case of a gentleman who, while talking, bit off a piece from an envelope. This little piece of paper, large enough to cover the rima glottidis, was drawn into his throat with his breath, lay like a valve upon his vocal cords and choked him to death.

Dr. W. Mendelson said that this question of suffocation as a cause of death had interested him a great deal. He thought that, in a certain number of cases, death resulted from inhibition of the heart by reflex action of the pneumogastric nerve. Any excessive excitation of the vagus might cause stoppage of the heart by inhibition. He thought this was the only way that these deaths could be explained. Evidences of suffocation were always found, because, though the heart had stopped, the centre of inspiration was still active and attempts at inspiration were made. The sudden and lightning-like rapidity with which these patients died, especially children, in whom the larynx was more sensitive, had led him to the conclusion he had given.

Dr. Curtis asked whether apoplexy might not be brought on by these suffocative attacks. Eighteen months ago an old woman had come under his observation with a rapidly developing cancer of the inferior maxilla. It was found impossible to keep her mouth open, and equally impossible to attempt extirpation of the growth. He had put her under ether with the idea of dividing some constricting bands by means of Paquelin's cautery, and, if possible, give some freedom of movement to the mouth. She took the ether well at first, and then suddenly stopped breathing. Under the circumstances it was impossible to get her tongue forward and so tracheotomy was performed immediately. Artificial respiration was resorted to, and, though breathing was restored, she never recovered consciousness and died during the night. Unfortunately, no autopsy was obtainable, but it was the speaker's opinion that she had suffered some form of cerebral hemorrhage during the attempts to restore breathing. There had appeared to be some paralysis, but the coma had been so profound that it had been difficult to ascertain its extent.

Dr. Biggs said that, with regard to those cases of death which were almost instantaneous, he agreed with Dr. Mendelson that they were due to reflex inhibition of the heart, and could be explained on no other hypothesis. Certainly suffocation could not cause death so suddenly. He had never seen a case of cerebral hemorrhage as a concomitant of suffocation. Such hemorrhage, did not, as a rule, occur during violent effort. Ruptures of the aorta and of aortic aneurisms were prone to occur during intervals of quiet. He had seen so large a number of cases of death by suffocation from foreign bodies in the air-passages that he had become impressed with the fact that innumerable instances of death in this way occurred in which the cause was unrecognized.

Dr. Mendelson related the history of a case of death from a supposed foreign body in the larynx. A woman had awakened

from sleep, had missed her false teeth, and had immediately come to the conclusion that she had swallowed them. Symptoms of distress and suffocation had come on. She started for the New York Hospital and was picked up by the ambulance, partly insensible. After the history had been elicited and her condition been taken into consideration, preparations were made for immediate tracheotomy. Before this could be effected she died. Her false teeth were found in a fold of her dress.

Ligation of the Carotid and Subclavian Arteries.

In the Transactions of the College of Physicians of Philadelphia for 1887, Dr. Wharton reported a case in which Dr. John Ashhurst, Jr., tied the right carotid and subclavian arteries for innominate aneurism, the patient making a good recovery. More than two years after the operation he is known to have remained well, and, as far as ascertained, has had no return of aneurismal symptoms since, a period now of more than three years in all.

In the *University Medical Magazine*, Jan., 1890, Dr. Ashhurst reports a case in which the right carotid and right subclavian arteries were ligated and in which the aneurism was manifestly aortic, though possibly involving the innominate artery also, and it therefore offered less prospect of benefit from operative measures than that above referred to.

P. A., aged 49, a machinist by occupation, was brought for advice in regard to a large aneurism on the right side of the chest, apparently originating from the ascending portion of the arch of the aorta. The patient had for twenty-two years been a hard worker in machine shops, his work including heavy lifting with the use of the sledge hammer, and sometimes occupying night as well as day. In October, 1888, after a period of unusually hard labor, he felt severe cutting pains in the right side of the chest above the nipple, and subsequently perceived pulsation in the same region. No tumor was noticed for six months, but in April, 1889, he observed a small swelling about three inches to the inner side of, and three and a half inches above the right nipple. This swelling pulsated and steadily increased in size, the tearing pains continuing, being particularly distressing in the region of the spine, and the patient becoming so short of breath that he was obliged to maintain the sitting posture during sleep. No exertion could be made without causing severe dyspnœa, but there was no cough. The tumor measured between three and four inches in each diameter.

The patient had received very careful medical treatment at his home, but without benefit, and was anxious to submit to any operation that might offer even a chance of relief. After watching the case for a few days Dr. Ashhurst resolved to adopt the method of double distal deligation, which in one case (Heath's) had afforded relief which lasted over four years, and accordingly, on October 19, 1889, he exposed and tied, with strong chromicized catgut, the right common carotid artery, in the usual position for this operation, above the line of the omo-hyoid muscle and the right subclavian in its third portion, where the artery crosses the first rib. The immediate effect of the operation was to produce great interference with circulation and respiration, the patient becoming black in the face and almost ceasing to breathe, so that it was necessary to suspend the administration of the anæsthetic and hold ammonia to the nostrils before proceeding to close and dress the wound. The patient's temperature fell to 95°+, and for some hours he remained in a very critical state, the heart laboring under the increased strain thrown upon it by cutting off the flow of blood through the tied vessels; but gradually reaction was established, and by the next day the alarming symptoms had entirely passed away. From this time the patient's progress was satisfactory; the pulsating tumor in front of the chest became smaller and beat less forcibly; the pain and dyspnœa disappeared; the ligation wounds healed firmly, though rather slowly; and on November 21, thirty-three days after the operation, the patient returned to his home in Reading, still, of course, the subject of an aortic aneurism, but much more comfortable than when he entered the hospital, and with the immediate risk of a fatal termination to his disease apparently indefinitely postponed.

Dr. Ashhurst states that his personal experience with the operative treatment of aneurism of the thoracic aorta is limited to three cases—that just narrated, one in which he tied the right and one in which he tied the left carotid artery. In the latter decided relief was afforded by the operation,

though the patient died some weeks afterwards, while in the case of right carotid ligation the effect of treatment appeared to be quite indifferent. For the immense majority of aortic aneurisms medical and hygienic treatment alone should be recommended, but in selected cases the question of operation may properly be entertained. Should the position of the aneurismal tumor on the left side of the chest render it reasonably certain that the innominate artery was not implicated, the choice should lie between ligation of the left carotid alone, as recommended by Dr. Cockle, and ligation of that and of the left subclavian as well; should such a case be presented to him again Dr. Ashhurst says that he should be disposed to employ the double operation, which, while not adding materially to the danger of the procedure, would certainly be more effective than carotid ligation only in diverting the blood-current from the sac. When the tumor appears on the right side of the chest the innominate is apt to be involved in the aneurism, and under these circumstances the double operation (on the right side, of course) is to be preferred.

As to the part of the subclavian to be tied, on either side, the third portion—beyond the scaleni muscles—should be chosen. On the left side, the first portion of the artery is so deeply placed as to be commonly inaccessible—indeed it has only been twice secured under these circumstances, once by the late Dr. Kearney Rodgers, and once by Mr. McGill—and in no case, on either side of the body, has the operation ever been successful, its statistics showing the ghastly record of twenty cases and twenty deaths. Ligation of the third portion of the subclavian is, on the other hand, neither a particularly difficult nor, with the modern improved methods of treating wounds, a particularly dangerous procedure, and though its statistical results, as derived from the records of historical surgery, are sufficiently gloomy, it offers, in connection with ligation of the carotid, enough hope of benefit to render its employment at least justifiable.

Trichinæ in Swine.

Science, Feb. 7, 1890, says (quoting the *Brooklyn Med. Journal*) that Professor E. L. Mark has recently published the results of the examination of 3,064 hogs raised in the vicinity of Boston, Mass. (*Report of Massachusetts State Board of Health.*) The examination extended over the five years 1883 to 1888. The results show that 14.07 per cent. of the males and 10.61 of the females were infected with trichinæ. Similar examinations of Western hogs have shown only from two to three per cent. to be infected. Professor Mark reaches the conclusion that this difference is probably due to the character of the food given to those raised in the vicinity of Boston, and presumably in the vicinity of other large cities. Of the fifty-six raisers of the hogs examined by him, fifty-one fed city offal. The source of the infection he believes to be in the uncooked meat found in kitchen garbage.

Buccal Gonorrhœa.

The following notes of a case of buccal gonorrhœa, reported in the *Medical Press and Circular*, April 30, 1890, are typical of their kind: A girl, 21 years old, after *coitus ab ore*, experienced on the following day a peculiar dryness of her mouth with a disagreeable taste; and the third day the tongue and the lips were swollen and puffy; on the fifth day she had difficulty in swallowing and fluid of a blood-stained, fetid character escaped. Then, besides, vesicles appeared on the lips and ulcerated spots followed by detachment of false membrane. All the tissues of the mouth were injected and swollen, secreting fetid blood-colored fluid; the breath was offensive, salivation being moderate. The false membranes, on examination, contained microbes which resembled the gonococcus. Glycerine, subnitrate of bismuth, and chlorate of potash were administered and effected a rapid cure.

Third District Branch, New York State Medical Association.

The sixth annual meeting of the Third District Branch of the New York State Medical Association was held at Syracuse, N. Y., June 19, 1890.

The programme was as follows:

President's Address, Popularizing Sanitary Science, J. G. Orton, Binghamton; Medicine, Past and Present, H. O. Jewett, Cortland; Malposition of the Epiglottis, with Specimen, Joshua J. Sweet, Unadilla; Fractures and Dislocations of Vertebræ, Chas. W. Brown, Elmira; Dermatitis Multiformis, W. H. Dunlap, Syracuse; Supra-pubic Lith-

otomy, W. A. Moore, Binghamton; Radical Treatment of Stenosis of Cervix Uteri, Ely Van de Warker, Syracuse; Epilepsy and Treatment, W. B. Morrow, Walton; Study of Hystero-Epilepsy, with report of a case, Leroy D. Farnham, Binghamton; Recent Advance in the Radical Treatment of Hernia, Nathan Jacobson, Syracuse; The Special Gymnastics for the Treatment of Rotary Lateral Curvature of the Spine, Leroy J. Brooks, Norwich; The Limits of Mental Therapeutics, H. D. Didama, Syracuse; The Test of Dugas in Dislocation of the Shoulder, Frederick W. Putnam, Binghamton; Antiseptics in Midwifery, F. O. Donohue, Syracuse; The Significance of Albuminuria Occurring During Pregnancy, F. W. Sears, Syracuse; Importance of Early Diagnosis in Affections of Spinal Cord and Brain, B. A. Church, Oneonta; Extirpation of the Breast, Emery O. Drake, Elmira; Complicated Retention of Urine, G. M. Allaban, Margaretville.

NEWS.

—Steps have been taken in Chicago for the erection and equipment of emergency hospitals in preparation for the World's Fair.

—A furnace will shortly be erected in the Central Cattle Market at Berlin for the burning of carcasses condemned as unfit for human food.

—Dr. A. B. Lyman has been elected to fill the newly-created Chair of History of Medicine in the University School of Medicine at Baltimore.

—Dr. Friedrich Salzer, well known as having been Professor Billroth's chief assistant for many years, has been appointed Professor of Surgery at Utrecht.

—The sum of about five thousand dollars has been given by a daughter of the late Dr. Crane to build and equip a surgical operating-room at Bellevue Hospital.

—An Intercolonial Australasian Medical Congress will be held in Sydney, probably in September or October, 1891. The President-elect is the Hon. Dr. MacLaurin.

—Edward J. Mealia, M. D., died at Brooklyn on June 6 at the age of thirty-one. He was a graduate of the College of Physicians and Surgeons, of the class of 1883.

—Cardinal Lavigerie is having negroes trained as medical practitioners at Malta, and several have already completed their education and proceeded to Central Africa.

—Charles Horton Wilkin, M. D., died in New York on Friday, June 6, at the age of thirty-four years. Dr. Wilkin was graduated from the College of Physicians and Surgeons in 1878.

—The Nebraska Christian University was established and opened its first term in Lincoln last autumn. This year it has added a medical school, which will commence its sessions in September, 1890.

—A hospital has recently been established at Bayonne, New Jersey. Every endeavor has been made to make it complete in every detail and to give it the most approved appliances available in a hospital of its size. It has a capacity of forty beds.

—The Senate of Hamburg has authorized the construction of a furnace, with columbarium, at a cost of $19,000. The funds will be collected by a local society which has been in existence for several years and working quietly in favor of cremation.

—John A. Bosch, M. D., died in St. Luke's Hospital, New York, on Friday, June 6, of pulmonary and laryngeal tubercular disease. The deceased was a graduate of the College of Physicians and Surgeons, of the class of 1885, and had served as a member of the house staff of Charity Hospital.

—By a recent decree every one who wishes to practice dentistry and "phlebotomy" in Italy must henceforth have taken a legally recognized degree in medicine and surgery. Dentistry will, for the future, be taught in the surgical department of such medical faculties as possess the necessary equipment for the purpose.

—A petition has recently been presented to the Austrian House of Deputies, asking for the admission of women to the philosophical and medical faculties of the universities of the empire. It is stated that the petition was signed by 4,812 people, including many leading representatives of literature, art and science.

—According to press dispatches the Royal oculist, Archduke Charles Theodore of Bavaria, has just concluded what he terms a month's holiday at Meran, in the Tyrol. As soon as his arrival became known afflicted peasants from all the valleys and mountains of the Austrian, Italian and Swiss Tyrol flocked into Meran and were treated gratuitously by the Duke, who, in four weeks performed fifty-three operations for cataract and one hundred and seventeen minor operations. H. R. H. the Archduke celebrates his fiftieth birthday on August 9, 1890.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

SOLUTION FERROUS MALATE retains its remarkable properties unimpaired when mixed with free acids, such as dilute sulphuric, dilute muriatic, and aromat. sulph. acids.

This acid solution (while it effectually disposes of its objectional properties) has the full therapeutic value of the tinct. chloride of iron, and is equally as good as a solvent and vehicle for sulph. quinia.

Free tannin is incompatible with SOLUTION FERROUS MALATE.

A combination of FERROUS MALATE with Salicylic Acid and Sodium which has been found of great value in obstinate cases of Rheumatism, where other remedies have disappointed. Reports of cases showing remarkably satisfactory results will be mailed on request.

John C. Baker & Co.

PHILADELPHIA.

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

GLYCOZONE

Is used as an internal remedy, or for local dressings. It is absolutely harmless; and Ozone is its healing agent.

GLYCOZONE, by its wonderful antiseptic and healing properties, not only prevents the fermentation of the food in the stomach, but it quickly cures the inflammation or irritation of the mucous membrane. It is a specific for disorders of the stomach: **Dyspepsia, Catarrh of the Stomach, or Gastritis, Ulcer of the Stomach, Heart-Burn.** Sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing CHAS. MARCHAND'S label and signature.

Prepared only by Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

A book containing full explanations concerning the therapeutical applications of GLYCOZONE, with opinions of the profession, will be mailed to physicians free of charge on application.

GLYCOZONE	¼ lb. bottle, retail price,	$1.00
	½ lb. " "	1.75
	1 lb. " "	3.00

SOLD BY LEADING DRUGGISTS.

ACUTE ARTICULAR RHEUMATISM.—TUBERCULOSIS FOLLOWING PLEURISY.—PNEUMONIA.[1]

BY J. M. ANDERS, M. D.,

PHILADELPHIA.

Acute Articular Rheumatism.

Gentlemen: This woman is thirty-nine years old, and her occupation is that of a domestic. She has been always sickly, particularly as a child. Two years ago she had an abdominal tumor removed. She had a bad attack of rheumatism in the fall of 1882, soon followed by signs of constitutional syphilis, falling out of the hair, iritis, and sore throat. The present attack of acute articular rheumatism came on suddenly. More frequently the onset is gradual. Another way in which rheumatic attacks begin, especially in children, is with heart disease.

When she was admitted to this hospital, about three weeks ago, her temperature was 104° F. I have noticed that when this disease has but several days of high temperature, followed by a rather sudden fall, relapses and complications are apt to be noticed. There is now profuse sweating, and a systolic murmur is heard at the junction, on the right side, of the second rib with the sternum; and this murmur is transmitted over the right carotid artery. There is no murmur near the apex, but one over the tricuspid valve.

The question now comes up: Is this an anemic murmur, or is it one due to rheumatic endocarditis? It is not anemic, because there is no venous hum heard, and the point of greatest intensity is not over the carotids. In the next place, she has dyspnœa and pain. If this murmur were due to interstitial change, it should be harsh, not soft and blowing as

[1] Delivered at the Philadelphia Hospital.

it is in this case. Again, there is very little, if any enlargement, of the left ventricle. Endocarditis occurs often in rheumatism. Some writers go so far as to say that it occurs in fifty per cent. of the cases. In pericarditis the pain in the region of the heart is increased by pressure, and pericardial friction sounds are heard, and there is also an increased area of cardiac dulness after the effusion occurs. In acute endocarditis the murmur is soft and blowing and never transmitted to the back. The remedy in this disease is salicylate of soda, 20 grains every two hours. After this has been taken for twelve hours, it is stopped during the remaining twelve, and fifteen grains of the citrate of potassium is taken every two hours. Some physicians recommend the benzoate of ammonium. If the heart is depressed the oil of gaultheria may be exhibited every two hours in fifteen-drop capsules with carbonate of ammonia. Concentrated foods should be given frequently. As a tonic a mixture of iron, quinine and strychnine should be given three times a day. The exhibition of the salicylate of sodium is to be kept up for a week after convalescence has set in, in doses of from ten to twenty grains three times a day, especially where the temperature falls early.

Tuberculosis Following Pleurisy.

This patient, a man, 28 years old, has been tapped twice on the right side for pleuritic effusion. There is still some thickening of the pleura on the same side, about the base of the lung. There is no dulness over the rest of the right side, but at the apex of the left lung there is tubercular infiltration. The question to-day is: Whether tuberculosis is more apt to follow than to precede a pleurisy? For a long time this question has been *sub judice* until now, when it is generally admitted that pleurisy is one of the more important causes of phthisis, if, indeed, it be not itself tubercular in nature.

Pneumonia.

This man is a bookbinder and forty years old. Eight years ago he had malaria and four years since he had a return of the same disease. For two months before this attack, he was ailing. He had a chill two weeks ago, and came into this hospital with severe pain in his side and a temperature of 104° F., which continued for five days. During this interval there was dulness on percussion, and bronchial breathing over the lower lobe of the right lung. He still has some dulness on the right side on percussion, and upon auscultation there are numerous sub-crepitant râles, indicating that the crisis is past; but his temperature is still too high to bear out this idea. The rusty sputum, the pain and dulness together with the auscultory signs on the right side indicated the existence of croupous pneumonia. As his bronchial breathing disappeared his expectoration became more profuse. Scarcely a symptom, then, remains of his illness but his high temperature. Some would maintain that this man is now tuberculous, but I believe that his lung will gradually clear up. It is, however, hard to give a correct prognosis while the man is in such a run-down condition as he is now.

Pneumonia is to be differentiated from capillary bronchitis, in which we have moist râles over both lungs; and also from œdema of the lungs, in which condition moist râles are usually numerous on either side. The diagnosis of pleurisy rests as much on general symptoms as it does on physical signs. At the beginning of pneumonia we have usually a rigor, pain below the nipple, cough, high temperature and great muscular prostration. All of these symptoms are more exaggerated than they are in pleurisy. Pneumonia gives dulness, but not as great in the later stages as pleurisy gives on account of the effusion; and in pneumonia we have bronchial breathing at the base of the consolidated lung, crepitant râles and the absence of pleuritic friction.

In the way of treatment this man has received carbonate of ammonium and alcohol, while his temperature has been lowered by the exhibition of quinine. For the pain hypodermic injections of morphine have been allowed. When the heart showed signs of weakness it has been stimulated with either wine or whiskey. The only drawback to the use of ammonium carbonate in this disease, is its bad effect on the stomach. When the patient has reached the stage of the disease arrived at in this case he is to be put upon quinine, and the iodide of ammonium, and, later, I shall add to this iron and strychnine. A great many physicians still adhere to the use of a poultice to the chest. This may be employed in hospitals among trained nurses; but the practical inconveniences attending its use in general practice makes the application of cotton wool to the chest—which will also

keep the skin moist and relaxed without needing to be so frequently changed—a far more pleasant and eligible application.

COMMUNICATIONS.

INFANT FEEDING.[1]

BY E. P. DAVIS, M. D.,

VISITING OBSTETRICIAN TO THE PHILADELPHIA HOSPITAL, PHILADELPHIA.

It is impossible to appreciate the problems connected with infant feeding correctly without a preliminary consideration of the digestion of the healthy infant. From experiments which I have recently conducted in the Philadelphia Hospital, I am led to believe that the digestion of the healthy nursing infant is not a hydrochloric acid, peptic digestion, as it is commonly taught and supposed, but that the milk is simply coagulated in the stomach by a ferment similar to that found in the stomach of the calf. By an examination of the stools of diseased babies suffering from intestinal catarrh, I found that, in proportion as the disease was severe and the stools excessively disordered, the proportion of undigested fat increased, while, as convalescence returned and the stools became more normal, the digestion of fat was better performed.

From the standpoint of clinical experience, pediatrists inform me that they are not prescribing pepsin as extensively as formerly, but that pancreatin and sodium bicarbonate have been found agents of decided value in treating dyspepsia in young children. It seems rational to conclude, then, that the stomach of the healthy baby is simply a coagulating bottle, which forms the milk into an exceedingly fine clot. By removing this clot from the stomach at various intervals after nursing, and by examining it under high powers of a microscope, I found that the clot consisted of albuminoids and fatty matter in a state of very fine subdivision. Bacteria were not present, and the clot was in a condition to be readily absorbed by the intestine. I found also that the same condition of affairs existed in the clots from the stomachs of infants fed upon diluted sterilized milk. We conclude that intestinal and pancreatic digestion is of paramount importance to the young child.

Turning now to the natural food of the healthy infant, we find mother's milk to be slightly alkaline in reaction, rich in fat, and considerably so in sugar, with a small percentage of albumin. When we search for a food most closely resembling this, we find that cow's milk differs from woman's milk, in containing less fat, less sugar, more albuminoids, and in having a slightly acid reaction. There is, however, no other food so closely resembling mother's milk.

Since the study of bacteriology, we are aware of a source of danger in cow's milk of which we were formerly ignorant. We know that whenever the average daily temperature reaches a point above 67° F., that albuminoid matter in milk, and in the water of ponds and streams, tends to decompose by fermentation. This fermentation, sooner or later, is attended by the presence of bacteria, and milk so fermented introduced into the stomach of the young child becomes a potent source of disease.

Sterilization of milk consists in destroying these germs by the application of a high degree of heat and pressure of steam; it is effected by the use of different forms of apparatus, one of which I show you; it consists of a tin box having shoulders about two inches above the bottom, upon which rests a perforated tin tray containing the bottles of milk; these bottles are corked by a rubber cork in the centre of which is a glass plug; water is put in the box sufficient to reach to the bottom of the tray; the bottles are filled with milk and corked, and the whole is placed upon the fire. As the milk heats, the glass plugs are removed, to allow the steam to escape, otherwise the bottles would break; after five or ten minutes the glass plugs are replaced, the corks are tightly pressed down, and the milk is boiled for twenty minutes or a half-hour. It is then put aside on ice to cool in the bottle in which it was sterilized, and when desired to feed the child a rubber nipple soaked in a solution of boric acid is slipped over the bottle, and the cork having been removed, the child is allowed to nurse. An equally good and simpler way is to cork the bottle with a well fitted plug of cotton; this prevents the bacteria from entering, but does not prevent the gas from escaping.

The sterilization of milk is effectual not only in destroying bacteria, but also in

[1] Abstract of an address before the Berks County Medical Society.

neutralizing tyrotoxicon. An instance occurred in the practice of my friend, Dr. Bennett, while at Atlantic City, where, in an institution for the care of infants, milk became poisoned by tyrotoxicon. None of the children were affected by the poison, as they were fed upon sterilized milk, while most of the mothers who drank the milk without sterilization were violently ill. It is evident that the best food for children will be cow's milk modified to resemble as closely as possible mother's milk and then sterilized.

The formula which seems best is one recently proposed by Rotch of Boston, which is as follows: Milk 1 ounce, cream 1½ ounces, water 5 ounces, milk-sugar 3½ teaspoonfuls. This is to be steamed in the bottle for twenty minutes, the bottle tightly corked with a cotton plug; after steaming remove the bottle. After it is partly cool, add half an ounce of lime water, then keep it on ice.

When a child is three or four months old there are several artificial foods which are very useful when mixed with milk, but for the nourishment of the nursing infant they are far from being the best substitute for mother's milk. In the case of children acutely ill milk should not be given at all, but barley water may be given combined with the white of a raw egg, and with whiskey or sherry wine. Free stimulation should be early employed in all acute diseases of infancy, and a child can be perfectly well supported by means of stimulants, barley water, rice water, or arrowroot water, or with whiskey and simply boiled water for twenty-four, thirty-six, or forty-eight hours, until the practitioner can empty the intestines of irritating matter, and thus give nature time to resume the digestion of milk.

Considerable difficulty is found in introducing sterilized milk for common use, from the fact that ignorant mothers do not understand its value, nor the way of using it. Efforts have been made to induce those who furnish large amounts of milk to keep sterilized milk for sale, but so far these efforts have been very little successful. In Philadelphia the Visiting Nurse Society has been sterilizing milk for poor children for a number of months, and has furnished over thirty gallons of sterilized milk. This is taken to the mothers by a trained nurse, the consumer paying for the cost of the milk, but not paying for sterilization, and in many cases not being able to pay for the services of the nurses. So far as I am aware, this is the first instance of the kind in which this has been done.

Of the value of sterilized milk there is no doubt, and it is safe to say that the infant mortality of the world has been reduced at least one-tenth by this process.

We do not claim that milk as taken from the cow always needs sterilization, but that in many cases, especially in towns and cities, it is an unsafe food for children unless so modified.

ELECTRICITY AS A REMEDIAL AGENT.

BY ANDREW GRAYDON, M. D.,
PHILADELPHIA.

Facts always carry more weight than assertion, demonstration than mere denial; the fair mind is always open to conviction from proof. And yet it seems characteristic of much human nature to condemn before testing; to find fault with and hunt for flaws in a line of action before any practical experience on its part has shown what there may be in it for good or evil. It is so much easier to condemn than to prove, especially if the critic is wedded to another method and blindly sets his face against any innovation. Prejudice stops impartial investigation, and generally adopts persecution as its weapon.

In our day the medical profession is divided as to the efficiency of electricity in the treatment of disease, and, strange to say, is split along the lines laid down. Strange, because we are hunting for health-giving forces, and should always be ready to receive every good agent and put it to the test. Those that have given electricity a trial in the spirit of fairness and have used it with the care and precision demanded by the rules which govern it, have either adopted it in appropriate cases, or, not wishing to do that, have given their testimony in its favor; whereas its bitterest opponents have no personal knowledge of it and have not taken the trouble to inquire into its principle. How many of its opponents have faithfully put it to the test of clinical experience? The results of such trials will bring demonstration and conviction that no amount of vituperation can shake.

Here is a case in point, that is typical of a large class met constantly in practice.

M. D., 32 years old, married 15 years, with one child 10 years old, and one miscarriage, presented herself to me with a history of excessive uterine hemorrhage continuing at intervals for the past three years. The bleeding lasted from fifteen to twenty days and was very profuse. There was no pain; simply flooding at the slightest exertion upon all occasions. The patient is pale, bloodless in appearance, emaciated to a degree and a type, in every respect, of profound and long-continued anemia. During this period of three years she has been under routine treatment and has derived no benefit whatever from it, being free from bleeding scarcely ten days in the month.

Examination showed an enlarged, flabby uterus, retroflexed, with a slight laceration of the cervix. She was first given galvanism, on alternate days, the positive electrode (Goelet's) in the uterus, 25 milliampères. Two applications of this was followed by an excessive hemorrhage, it being about the time for one of her outbreaks. At the cessation of this, on account of her prostration, she was given intra-uterine Faradism. This was changed for galvanism, but always with ill-results, so much so that the Faradic current was the one selected for her case. Her general improvement was marked and steady, and of a degree surprising to herself.

The first menstrual period after beginning treatment was five days in duration and the flow much diminished in quantity.

She was under treatment three months, the application being made twice or thrice weekly. At the end of that time she expressed herself as being better than ever in her life. Her menstrual periods appear at regular intervals of a month, last about five or six days and then cease. She has gained in weight, color and spirits.

Though I generally prefer to use positive galvanism in these cases, on account of its hemostatic action, in hers I could not; since it seemed to aggravate her condition. What high intensities would have done I could not prove. She could not endure more than forty milliampères. She was under this electrical treatment for three months and under the regular (?) management three years. Contrast the results.

The following case represents another class. A young woman came to me with this history. Aged 24; married one and a half years; never pregnant; for the past two or three years she has been suffering with a severe pain in the right groin, of a sickening nature. This is intensified at her menstrual periods, and is preceded with an aggravating headache for a week before the flow is established. Her condition is such as to force her to go to bed during the first three days of each month. The menstrual discharge continues for more than a week, intermittent, halting, with clots, never free. Coition always unendurable on account of the pain. Examination showed the right ovary to be prolapsed, enlarged and exquisitely painful. The soreness was so great as to cause the woman to spring partly from the examining chair when the organ was touched. This condition had been verified, before she came to me, by a thoroughly competent man, who exhausted routine treatment, and told her she could get no relief until the ovary was removed.

She was given galvanism at once. A positive carbon button wrapped in clay, cotton, etc., was applied against the inflamed ovary, and a negative clay pad was placed on the abdomen. At first the current was given three times a week, 25 to 50 milliampères. After two applications the sensitiveness of the painful spot began to abate, and at the end of the second week of treatment the soreness had entirely disappeared. The first menstrual period after using this treatment came on "without any pain or discomfort," and continued for one week. The woman's general condition she reported as being better than it had been for years.

She received two treatments between this and the succeeding menstrual epoch, which appeared on time, without pain, and lasted less than a week. At these two séances the current measured from 80 and 100 milliampères respectively. Latterly she has been treated at intervals of a week or ten days, with a current varying between 100 and 175 milliampères, of 5 to 7 minutes' duration. At her last visit she said she had done her washing without any pain for the first time in years. The pain on coition had also disappeared. She had taken no medicine whatever, except an aloin pill occasionally to regulate the bowels.

There is an analogy between this case and that reported by Dr. Rockwell (*Medical News*, Jan. 25, 1890), with this very important difference: My case has been relieved with the *ovaries intact*, and in Dr. Rockwell's the relief was given in the same way, by the same remedy, but not until another operator had removed the unoffending or-

gans, or *after mutilation.* A tremendous difference, as any one will admit.

We may be allowed to draw the same conclusions with him, when he says: "It is self-evident that an agent like the galvanic current, possessing such a marked influence over so many forms of pain of obscure origin, *should precede* (Italics mine) rather *than follow* severe proceedings for their relief." The two illustrative cases are their own demonstration of the value of electricity, and I place them against the theoretical objections of its opponents. With the support of men like Keith, Spencer Wells, Playfair, Bartholow; the developments of Apostoli; the dictum of Keith when he declares it almost a criminal offense to remove the ovaries or to do a hysterectomy for a bleeding fibroid before electricity has been tried; the accumulating results from earnest and honest workers everywhere; with all this which carries its own convincing force "dogmatic and theoretical assertions" of the non-value of electricity are worthless.

1338 Walnut Street.

Reports of Clinics.

PRESBYTERIAN DISPENSARY, CHINANFU, CHINA.

DR. ROBERT COLTMAN, JR.

Phimosis.

This man, a painter, forty-six years old, comes to us for a not unusual affection, namely phimosis. In his case, however, as you see, the orifice of the urethra through the prepuce has become so diminished in size as materially to interfere with the act of urination. This is a simple uncomplicated case, due to gradual constrictive growth of the prepuce. Phimosis to a moderate degree may exist without serious inconvenience, and in a majority of cases gives rise to no difficulty of urination; but occasionally, after gonorrhœa, or more frequently after chancre, the tissues of the prepuce become infiltrated with serum, which, undergoing organization, forms a permanent circular growth and finally renders urination next to impossible. This patient can urinate only a drop at a time. The proper treatment is to circumcise him; but he objects so strongly to this that I have consented to simply slit up the prepuce. This is not as elegant an operation as circumcision, but is equally effective. Avoiding these two larger veins, I, with blunt-pointed scissors, cut through the constriction by several short snips and the operation is ended. In these cases there is frequently very free bleeding, and I prefer scissors to a knife, as they cause less hemorrhage, I place a little styptic cotton against the cut surfaces, and will direct the man to return to-morrow, when we will dress the wound with a five per cent. solution of carbolized oil until the parts heal.

Ulcer of the Cornea.

This young woman, twenty-three years old, tells us her eyes pain her very badly; and upon opening the lids of the right eye we don't wonder at their paining. We find a large circular ulcer, a line or more in diameter, directly in front of the pupil; the cornea is infiltrated below, and the conjunctiva is very red. The left eye also has a smaller ulcer on the left of the pupil somewhat below the centre of vision. This cornea is much clearer than the other, and the ulcer is of more recent date. She has severe photophobia, and is suffering greatly from neuralgia of the supra-orbital nerves. I can elicit no specific history. Her tongue is heavily coated, and she says her bowels have not been moved for three days. We will give her two compound cathartic pills, to be taken at once and to be followed in the morning with a two-drachm dose of Epsom salts. For an application to the eyes I shall use two drachms of iodoform, finely pulverized, to half an ounce of castor oil. This we will prepare freshly, and place a few drops in each eye with a camel's hair brush, I shall also paint tincture of iodine over each eyebrow, which will considerably relieve the neuralgia; and after her cathartic has acted we may prescribe an anodyne. Absolute rest is necessary. Should there be danger of perforation, which seems not unlikely, we will anticipate it by a paracentis of the anterior chamber.

Ulcer of the Cornea.

This man, thirty-seven years old, a farmer, presents a case of ulcer of the cornea, but one very different from that of the patient who has just left us. This man first came here ten days ago, and has been under continuous treatment. He was exposed to a severe dust-storm some two weeks ago, and his eyes became much inflamed.

When I first saw him both eyes had several small ulcers above the centre of vision. On examining the upper lids, I found them both very rough with large granulations. These I scraped as smooth as possible and then applied a solid stick of acetate of lead to the bleeding granulations. Oculists would probably say that this procedure was ruinous, but it worked like a charm. The granulations yelded rapidly and the eyes began to improve. We are told in the books not to use lead or silver in treatment of ulcers of the cornea and as a rule I suppose it is a good precept; but there are occasions when it does not do to adhere so closely to sage authorities; and one has to decide all cases on their merits. I would never advise a lead solution as an application to a corneal ulcer, in fact, I would condemn it; but in an ulcer complicated with rough lids I should, as in this case, first scrape the granulations and then apply a crystal of lead acetate to the lid. For all small uncomplicated ulcers I use a solution of silver nitrate, one quarter-grain to a fluid ounce of water. Two drops of this solution is placed in the eye not oftener than twice daily. The constitutional treatment should be as is indicated. Absolute rest is always enjoined.

Some may object to this treatment as almost homœopathic; but in an experience of several hundred cases treated in this way, I have had universal success. In a number of cases otherwise treated, or by rest alone, I did not get equally good results: the time for a cure being much longer; and I am forced to the conclusion that this is an excellent application in the cases indicated. We shall treat this patient now upon this plan.

Opium Habit and Impotency.

This man is a magistrate, fifty-two years old, and comes to us claiming to be impotent. He says he uses an ounce of opium daily and drinks from three to five pints of huang-chin in twenty-four hours (strength about equal to claret). His bowels move once in from five to seven days. Considering the amount of opium he uses and wine he drinks it seems a wonder he is alive. To look at him you would think he was enjoying robust health; and in fact he says that with the exception of occasional attacks of vomiting, he does enjoy good health. As to the treatment of his impotence, that is useless unless he will reduce his opium. He says he will attempt this; but I know from experience that he will fail. He will try to reduce at the rate of half a drachm every other day. There have in my experience been a few patients who have successfully done this, but the large majority have failed. I shall prescribe for the man a pill containing ℞ Extr. nucis vom., gr. ¼; quinæ sulph., gr. i; extr. gentian, gr. ij; which is to be taken three times daily for six days, and, if he succeeds in gradually reducing his opium and wine, we will afterwards prescribe the hypophosphites and strychnia.

HOSPITAL NOTES.

KENSINGTON HOSPITAL FOR WOMEN.

SERVICE OF DR. CHARLES P. NOBLE.—REPORTED BY DR. H. E. APPLEBACH.

Saline Cathartics in Post-operative Peritonitis.

Reta P., colored, 22 years old, was admitted to the Kensington Hospital for Women with an enlarged and inflamed right ovary. She had been treated for some time by her physician, a very able man, without obtaining relief. After examination at the Hospital, removal of the right uterine appendage was advised. May 3, 1890, the ovary and tube were removed, a drainage-tube was introduced and the wound was dressed in the usual aseptic manner. Two days later the patient began to manifest signs of a developing peritonitis, with quite marked pain and tympany, the temperature rising and the pulse rate increasing. The discharge from the drainage-tube became quite gummy, evidently almost pure plastic lymph. One ounce of a concentrated solution of citrate of magnesia was given every hour until the bowels were freely moved, which resulted in the disappearance of all the symptoms as if by magic. Since then the patient has had an uncomplicated convalescence.

After abdominal operations, when purgation is necessary, it is not advisable to administer so large a quantity of fluid as is contained in the ordinary preparations of the citrate of magnesia. At the suggestion of Dr. Noble, the chemist connected with

the Hospital has prepared a concentrated solution of the citrate of magnesia, four ounces of which are equivalent in strength to twelve of the officinal preparation. This has been found to be an efficient and convenient preparation, and is very much more palatable than any preparation of Rochelle or Epsom salts.

The use of saline cathartics in the treatment of peritonitis following abdominal operations, has become so general, and the good effects obtained so constant, that it is of importance to have a palatable and at the same time an efficient preparation of the salines for use. This concentrated solution has also been in constant use, as a purgative, during the convalescence of operation cases.

PERISCOPE.

On Subcuticular Suture.

In these days when the surgeon's knife is much more frequently demanded than formerly, it is often necessary, in the more exposed parts of the body, to leave as little trace of its use afterwards as possible. This is especially desirable in operation wounds about the face or neck of women, for in them we cannot hope, nor is it desirable, that as youth passes into the fuller development of maturity, the growth of hirsute appendages will eventually conceal the mark which the operator has been obliged to make. Much has been gained in this direction by the introduction of antiseptics in surgery, by means of which we can in general insure an immediate union of the wound's edges. We thus substitute for the cicatrix, often thick and wrinkled, of a wound that has healed by granulation, the delicate, pliant and frequently almost unnoticeable scar which we seek to obtain in union by the first intention.

In a paper read before the Surgical Section of the British Medical Association at its last annual meeting, held at Leeds, Mr. Kendal Franks referred to the satisfactory results he had obtained, in this direction, by the employment of subcuticular sutures.

In the neck, for instance, when such a wound is small, and lies in a natural fold of the skin, the scar itself requires no concealment, for it would pass unobserved were it not that on both sides of it small points are most distinguishable, red at first and eventually white, which mark the points at which sutures have been inserted. Mr. Franks has frequently endeavored to avoid these marks by employing strips of sticking plaster to keep the edges of the wound apposed instead of resorting to stitches, but was obliged to abandon this method on account of the difficulty of insuring a perfectly aseptic condition of the parts; because when dry, no sticking plaster is reliable, and if it is rendered aseptic by immersion in an antiseptic solution its sticking properties are destroyed. And thus we run the danger either of not keeping the edges of the wound properly apposed, or by allowing the wound to become septic to delay union, in either of which cases the wound must heal by granulation, and the defacement caused by the scar becomes worse than that which would be due to the suture points. These considerations induced Mr. Franks to seek for some other plan which would insure union by first intention and would at the same time abolish the evidences of the needle. These points are gained by the use of a subcuticular suture. A fine curved needle is required, preferably one of Hagedorn's needles, and very fine catgut. The suture must be a continuous one. The needle is inserted horizontally, that is, parallel to the surface of the skin, at the cut edge of the wound, not vertically to it, and at a distance from the cut edge, as in the ordinary suture. Mr. Franks describes the method of inserting the suture in the *British Med. Journal*, Feb. 22, 1890. He says:

"I begin at a point about quarter of an inch from the upper angle of the wound. The needle is passed horizontally underneath the epidermis of the skin into the cutis vera and emerges again from the cutis vera at the angle of the wound itself. It is then passed in a similar manner into the cutis vera alone of the opposite side of the wound, beginning at the extreme angle and emerging at a point a quarter of an inch from it. The catgut is drawn through so as to leave just enough at the first point of entrance to enable it to be tied to the portion of the suture which holds the needle. This forms a standing point. The needle is again inserted horizontally into the true skin, beginning immediately below the first point of entrance and comes out again a quarter of an inch lower down; it is then passed similarly into the other edge of the wound, at a point corresponding exactly to the last point of emergence on the opposite side, being brought out again quarter of an inch lower down.

This method is continued until the lower angle of the wound is reached.

"It will thus be seen that the suture, before it is tightened, has the appearance of a ladder; the visible portions of the suture forming, as it were, the rungs; and if the suture has been properly inserted, these rungs will all be parallel. Now, when the suture is tightened, in the same way as we draw tight the lace of a shoe, you will see that the edges of the wound come accurately together, without the suture being visible or a single needle point appearing. The suture, you will observe, gives the wound a very slightly wavy appearance, which, however, eventually disappears. A knot may now be placed on the free end of the catgut and the rest cut off. Mr. Franks used this suture for several years, and his colleagues in the Adelaide Hospital have adopted it, and we are all satisfied with the results. It is certainly a little more difficult and a little more tedious than the ordinary suture, and therefore it is not employed for wounds in the covered parts of the body; but in the exposed parts and chiefly in the neck, it undoubtedly reduces the ultimate mark to a minimum.

"There is one class of cases in which this suture is of the greatest value; namely, in the removal of scrofulous glands from the neck. Especially is this the case with girls; but it is also most desirable in boys who desire to enter the army, where the regulations of the service prevent their adopting those means of concealment with which nature would provide them, and where the presence of an unsightly scar would arouse the suspicions of the medical examiner to the point of rejecting the candidate.

"A very great and salutary impetus was given to the more radical treatment of these affections by Dr. Clifford Allbutt and Mr. Pridgin Teale, of Leeds, and excellent results have been obtained by the early opening and complete scooping out of suppurating scrofulous glands, as advocated by them; but Mr. Franks believes that even more rapid and better results will be gained in those cases which we can approach even at an earlier stage, before the cheesy centres in the glands have broken down into abscesses and before the capsule of the glands has contracted adhesions to the surrounding tissues, while the gland is still hard and movable, then, through a small incision, perhaps an inch long, or an inch and a half, the gland can be easily enucleated, like the walnut out of its shell, and the resulting wound kept together by a subcuticular suture will leave a cicatrix which even a close scrutiny will only just detect."

Iodine as a Remedy for Vomiting.

M. Darthier (*L'Union Médicale*, December 10) bears testimony to the value of tincture of iodine administered internally for the relief of vomiting, a remedy recommended by the late Professor Lasegue in the vomiting of pregnancy. The author had observed its use in nineteen cases, eleven of which were tubercular subjects, and found that it is of more value in the vomiting of early phthisis than in that of the later stages of this disease. At the same time he gives instances of advanced cases with obstinate vomiting where the symptom was largely controlled by the drug. Amongst other cases he gives one of bronchial dilatation (subsequently fatal from acute tuberculosis) in a female, who, for three weeks, had regularly vomited after every meal. From the date of commencement of the use of the drug, she ceased to vomit, and after a week's treatment, which was not productive of any signs of iodism, was completely cured of the symptom. Apart from phthisical vomiting, M. Darthier finds it useful in alcoholic gastritis, in ulcer of the stomach, and in the vomiting of pregnancy, and of chlorosis, instances of which are recorded. He says that the majority of the patients take the iodine with pleasure; it often produces an agreeable sense of warmth in the stomach, lasting from five to twenty minutes. The dose is ten drops dissolved in 125 grammes of water, taken in three portions immediately after meals. In a certain number of cases, symptoms of iodism are produced, chiefly coryza; but a good many patients do not experience any such inconvenience from it.

Dr. Frederic Taylor, of Guy's Hospital, confirms Dr. Darthier's views. (*Lancet*, Feb. 1, 1890.) Dr. Gaunt, of New York (*Amer. Jour. of Med. Sci.*, April, 1883), found it valuable in vomiting from a variety of causes, acute indigestion, phthisis, hysteria, septicæmia, nephritis, acute catarrhal gastritis, drunkard's gastritis, and many cases of gastro-intestinal disturbance in children. He gave 3 to 5 minims of compound tincture of iodine at intervals of 15 to 30 minutes, or sometimes less frequently; to infants, 1 minim or half a minim. After reading Dr. Gaunt's paper, Dr. Taylor tried it in several

cases, and since then it has been a good deal used at Guy's Hospital. He administers it in doses from 3 to 5 minims in two to four drachms of water every half-hour, or every hour, for six or eight hours, and then, if it is necessary to continue it, he gives it at longer intervals. But he has found the result often attained after the second or third dose. He has used it, and known it used, with success in the vomiting of Bright's disease, in cerebral vomiting, in vomiting after chloroform, in the vomiting of migraine, in vomiting from gastric disease, and in other instances. He says that it does not always succeed, but that it has done good much more often than other drugs commonly used for this purpose, and that it is really a valuable addition to our means of treating cases of this kind.

Misuse of Hypnotism.

The *Lancet*, March 15, 1890, says that at Nuremberg a case of some public interest has recently been tried in the police court. A commercial traveler while in a restaurant told the waitress to look steadily at the white of his eye, and hypnotized her. On a second occasion he repeated the experiment, but this time the sleep produced was so profound that a medical man had to be called, who had the utmost difficulty in rousing the girl. The commercial traveler was accordingly summoned to appear before the magistrates, and the severe sentence of eight days' imprisonment was passed on him, which will probably be efficient in checking similar performances in that region. In France the practice of hypnotizing people for amusement seems to be very common, and unpleasant consequences are frequently reported. At a supper party in Paris recently one of the company hypnotized a girl, and was unable to rouse her. She was consequently taken to the house of a medical man, and after a time she recovered consciousness. The whole party were taken into custody by the police, and were not released until next day. Even when hypnotism has been practiced by competent medical men for remedial purposes, unpleasant accidents and ulterior consequences have again and again occurred, so much so that recently an order has been issued by the French Government prohibiting surgeons in the army and navy from practicing it. It ought to be distinctly understood both by the profession and the public that hypnotism is not devoid of danger at the time, and not infrequently has permanently impaired the moral and emotional control of patients. A medical man is bound, before recommending hypnotism for a patient, to weigh the question as carefully as he would that of the advisability of administering an anæsthetic.

Abrin.

Abrin is obtained from the seeds of the Indian licorice (*Abrus precatorius—jequirity*). It is a brownish-yellow powder, soluble in water. Abrin is an albuminoid or proteid substance, belonging to the class of unorganized ferments, and is exceedingly poisonous.

Professor Kobert, of the Dorpat University, is now subjecting abrin to a thorough pharmacological investigation. According to the preliminary communications from the investigator in *Merck's Bulletin*, April, 1890, the lethal dose, intravenously, is only 0.00001 gramme to each kilogramme (1 to 100,000,000) of the animal's weight. The enormous toxicity of this substance, therefore, calls for extreme caution in its keeping, handling and exhibition. Of therapeutic interest is the fact that Professor Kobert succeeded in inducing the well-known "jequirity ophthalmia" with abrin. This appears to disprove the older, bacillary or bacterial, theories of "jequirity"—poisoning, set forth by Carnil, Berlioz and Sattler, as quoted in the *National Dispensatory*.

Acetophone.

Acetophone, or methyl-phenylketone, which has been employed chiefly by some French physicians as a hypnotic, has recently been studied by Dr. S. S. Kamenski (St. Petersburg Dissertations, No. 70, 1888-89). The results of his researches are stated in the *Quarterly Therapeutic Review*, Jan. 1, 1890. He finds that it lowers the sensibility and interferes with reflex action. Large and medium doses produce a moderate amount of sleep. It quickens the heart's action, probably by stimulating the accelerator nervous apparatus. It increases the irritability of the respiratory centre, except in large doses, which may arrest respiration altogether. It lowers the blood-pressure by its action on the vaso-motor centre and by weakening the heart's action. Medium and large doses lower the irritability of the brain, and even small doses have a similar effect on that of the cord.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

BULLOCK'S BLOOD IN THERAPEUTICS

In a paper read before the Philadelphia County Medical Society, March 26, 1890, Dr. F. E. Stewart, of Wilmington, Del., presented an excellent synopsis of the recent history of the use of animal blood as an article of diet for persons under the care of physicians. He discussed the difficulties surrounding the use of bullock's blood, fresh or dried, and referred to certain manufactured articles, the essential ingredient of which is supposed to be blood, alcohol and glycerine. After further noting several French preparations of dried blood, in connection with the "Sanguis bovinus exsiccatus" of the *U. S. Pharmacopœia*, Dr. Stewart went on to describe a preparation which he has recently devised, and which he calls "Hemoglobin Compound."

The preparation consists of fresh defibrinated bullock's blood and extract of malt, of each three fluid ounces; glycerine and whiskey, of each one fluid ounce. This is mixed together. Of this mixture twenty drops may be given three times daily, and the quantity gradually increased until one or two tablespoonfuls are taken at each dose. It may be given undiluted, or administered with milk or water.

Dr. F. G. Deveraux, of Kezar Falls, Maine, who has been using the compound, finds that if fifteen drops be mixed with five teaspoonfuls of milk, and allowed to stand, it soon digests the milk, and an unsightly mixture results. He, therefore, advises that when it is given in milk, the mixture should be administered immediately.

When prepared as described above, hemoglobin compound remains permanent indefinitely, even when exposed to the air in a loosely stoppered bottle.

Shaken in the bottle, so that a thin layer can be inspected as it flows away from the neck, the preparation is of a bright garnet-red color, and of a rather thin, syrupy consistency. It has the "molasses-candy" odor and taste peculiar to the extract of malt. There is no appearance, odor or taste of blood.

In administering the preparation it is well to commence with a minimum dose, carefully watching the condition of the stomach, to correct any tendency to nausea if it exist. Usually, the preparation is tolerated by the stomach. In cases of great exhaustion ten to twenty drops may be given every half hour, for three or four hours; then one or two teaspoonfuls every three or four hours. For infants, from three to ten drops in each feeding is the dose. This may be dropped in the bottle, or, in case the child nurses at the breast, it may be given in a little diluted milk and lime-water after the child has been fed. Ordinary cases requiring tonic treatment may commence with a teaspoonful three times a day, and gradually increase the dose to a tablespoonful.

Hemoglobin compound is not a patent or proprietary medicine. It is strictly a pharmaceutical preparation, and introduced in conformity to all the requirements of science and the demand of the code of ethics. In order to have a uniform article prepared, Dr. Stewart has placed its manufacture in the hands of a firm of manufacturing pharmacists; but he has published the true formula, and any one has a right to manufacture the article and to call it hemoglobin compound, or anything else. But Dr. Stewart naturally feels that a good article is more likely to come from a firm that has large facilities for making and selling it than from persons who might have to prepare it in very small quantities, with correspondingly smaller facilities.

We call attention to this preparation because it appears to be a valuable addition to the dietetic articles now in use by physicians, and because the materials required for making it and the manner of combining them is plainly as stated to the whole profession, and no manufacturer making it can get any advantage over any other except such legitimate advantages as may be secured by preparing a good article and bringing it the notice of those for whom it is intended. Whoever may do this will do a good service to the profession and is entitled to its appreciation.

CHOLERA IN SPAIN.

About the middle of June it was reported that Asiatic cholera had appeared in Puebla de Rugat and other places (Albaida, Benigamin, Castalla, Carcagente, Gandia and Jativa), in the provinces of Valencia and Alcante, on the eastern side of Spain, but not on the coast, and on June 18 a few cases were said to have occurred at Malaga, about three hundred miles distant and on the southern coast. The latest reports are that the number of cases is growing less and it is to be hoped that the disease will disappear.

It is rather curious in connection with this reported outbreak that it has occurred in a rather mountainous part of Spain and not in close connection with any active seaport. The news from Malaga may be erroneous, and it is also possible that that from the small towns or villages on the east is much exaggerated.

MISMANAGEMENT OF THE PHYSICIANS' REGISTRATION ACT.

In the last issue of the REPORTER attention was called to the defects of the law for the registration of physicians in Pennsylvania and to the manner in which certain of its provisions have been neglected by the Prothonotary in Philadelphia. Following this, the Prothonotary and his clerk made statements which were published in the daily papers of this city and which were made to appear as denials of the charges contained in the REPORTER. The weakness of these seeming denials was probably apparent to those who read them; but, in order to make the matter clearer, the Editor of the REPORTER, accompanied by his representative, who was detailed to obtain the facts already published, and a representative of one of the most influential Philadelphia newspapers, visited the Prothonotary's office on June 21, and there confirmed the truth of every one of the statements made last week in this journal and secured an acknowledgment of their correctness from the clerk of whom the Prothonotary had said that he could "satisfactorily refute them."

As a result of the action of the REPORTER it was pleasant to note that great earnestness was being displayed in the Prothonotary's office to correct the errors which we had pointed out, and we sincerely hope that hereafter the provisions of the law—which is so carelessly worded as to demand the greatest care in its execution—will be more closely observed than they have been heretofore.

In saying this, we may add that the attitude of the REPORTER towards the Prothonotary and his clerk in the present exigency is

not meant to be that of a persecutor. It is not our desire to discuss men's motives; but it is well within our province to make an effort to correct errors or wrong-doing in connection with matters affecting the standing of the medical profession and the health of the community. Success in any such effort depends so much upon a reputation for making no charges which cannot be established, that it seemed proper in the present case to force an admission of what the Prothonotary had denied, and to do this in the presence of an impartial witness.

We regret that the unwise action of the Prothonotary and his clerk have compelled us to dwell longer on their delinquencies than we would have wished. Confession and amendment may be reasonably expected of public officials who have exposed themselves to such criticism as the REPORTER has made; and if hereafter the Prothonotary will do fully what the law commands, and what his fellow-citizens have a right to expect, the REPORTER will be very glad to give him the credit he will then deserve.

SANITARIUM ASSOCIATION OF PHILADELPHIA.

The Sanitarium Association is one of the most interesting charities carried on in the city of Philadelphia. It has a place at Red Bank, on the Delaware river, a few miles below Philadelphia, to which, every day during the summer, suffering and debilitated children are taken without charge in steamers belonging to the Association. There they are watched over by careful guardians, and any sickness suddenly occurring among them, or development of sickness already present, is attended to by physicians engaged by the Association. In this way every summer thousands of children, with their mothers who are too poor to themselves afford the luxury of this great means of refreshment, find recovery placed within their reach. This charity has attracted a great deal of attention and much sympathy, as might have been expected from its character, and as is understood in this city by the reputation of the men who conduct it, and who have contributed their means to make it possible.

Medical men understand how often the refreshing air from the water, as well as removal from the heated quarters of a large city, are the indispensable conditions of preserving the lives of little children, and will be able to understand how thoroughly a work of this kind is in the interests of some of the most unfortunate and most helpless of our fellow-beings, and how worthy of imitation in other parts of our country is this successful example of it.

Philadelphia is not the only city in which the children of the poor are provided with means of escape from the trials of the city in summer; but there is no place we know of in which this form of relief and aid is administered so thoroughly and so judiciously, or where such perfect facilities are afforded by those who contribute to it.

There are few large cities which are not so situated with regard to considerable bodies of water as to make it possible for them to adopt some means similar to those of the Sanitarium Association of Philadelphia for the benefit of little children; and it may be that if the attention of physicians is called to the matter, they may be prompted to taking steps which will lead to a wider extension of this beneficent work.

END OF THE VOLUME.

With the present number of the REPORTER we reach the end of the Sixty-Second Volume; and it gives the publisher pleasure to say to its readers that the time covered by the volume has been one marked by many evidences of prosperity. The already large circle of readers of the REPORTER has increased and is just now increasing at a rapid rate. The Editor will continue to try to make it deserve the approval of his professional brethren, by representing what he believes to be their best interests, without fear and without favor.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

CLINICAL DIAGNOSIS: THE BACTERIOLOGICAL, CHEMICAL AND MICROSCOPICAL EVIDENCE OF DISEASE. By Dr. Rudolf v. Jaksch, Prague. Translated from the second German edition by Dr. James Cagney. With Appendix by Dr. William Stirling. With numerous illustrations, partly in colors. 8vo, pp. 398. London: Chas. Griffin & Co.; Philadelphia: J. B. Lippincott Co., 1890. Price, $6.50.

Dr. Jaksch's work on Clinical Diagnosis will be welcomed by students in this country, now that it has become accessible to English-speaking students by Dr. Cagney's able translation.

The book is thoroughly original and well up to date. The book is one that has earned great reputation in Germany and the English edition contains additions and explanations by the translator and supplemented by a valuable appendix by Dr. William Stirling, the translator of Landois' well-known work on physiology. The book abounds in excellent illustrations, many of which are colored. Special attention is given to the bacteriology of the blood, sputum and feces; and a chapter is devoted to the methods of bacteriological research.

VERHANDLUNGEN DER BERLINER MEDICINISCHEN GESELLSCHAFT AUS DEM GESELLSCHAFTSJAHRE 1889. Transactions of the Berlin Medical Society for the year 1889. Vol. XX. 8vo, pp. 476. Berlin, 1890.

The present volume contains the proceedings of the Society at its meetings between January 9 and December 18, 1889. The first part includes two hundred and sixty-two pages, and is taken up with the demonstrations, the minor papers and the discussions upon them; the second part, which comprises two hundred and fourteen pages, is devoted to the more important papers. The essential parts of several of the latter, such as "The Prophylaxis of Tuberculosis," by Georg Cornet, have already been given in the Reporter. The volume contains, as usual, a valuable synopsis of current scientific medicine.

LYMPHATIQUES DES ORGANES GÉNITAUX DE LA FEMME. Lymphatics of the Genital Organs of Women. By Dr. Paul Poirier. 8vo, pp. 60. Paris: Office of the *Progrès Médical*, 1890. Price, 2 francs.

Poirier describes the methods of making injected preparations of the lymphatics of the vagina, uterus, Fallopian tubes and ovaries, and gives beautiful woodcuts, almost like steel engravings, of the different preparations. The injecting fluid employed is mercury, and the method that of Sappey.

The author discusses the part played by these lymphatics in cellulitis and pelvic peritonitis. He refutes the theory of Lucas-Championnière, that the lymphatic trunks are the path of infection in purulent salpingitis and ovaritis; for, he says, if that were the case, the lumbar glands, which are in direct communication with the superior lymphatic trunks of the uterus, should be at the same time inflamed and in a condition of suppuration; but he does not know of a case in which this has been noted. He concludes that infection is by the mucous membrane, "at least for a certain number of cases;" but he is inclined to think that when the lymphatic system of the uterine peritoneum is better understood an important rôle will be accorded to it in the pathogeny of salpingitis.

ÉTUDE ANTHROPOMÉTRIQUE SUR LES PROSTITUÉES ET LES VOLEUSES. Par le Docteur Pauline Tarnowsky. Anthropometric Studies in Prostitutes and Female Thieves. By Dr. Pauline Tarnowsky. With twenty-eight illustrations. 8vo, pp. 226. Paris: *Progrès Médical*, 1889. Price, 5 francs.

Dr. Tarnowsky's studies in the field of anthropometrics is a valuable contribution to this science. Large opportunities for studies have been afforded her in the hospital for prostitutes at Kalinkine, and the prison of Litowski Zamok. The subject is dealt with exhaustively. Measurements of the skull, of the various features of the face and casts of the jaw are all carefully considered. The work is enhanced by a number of illustrations taken from photographs. The first part of the work is devoted to anthropometric studies in prostitutes; and the latter part to female thieves. These Dr. Tarnowsky classes as, 1, professional thieves; 2, prostitute thieves; 3, psychopathic thieves; and 4, occasional thieves. Numerous tables and extensive statistics serve to make the book very complete.

Correspondence.

Reduced Rates—A Disappointment.

To the Editor.

Sir: I desire to state that many of the profession of America who contemplate attendance at Berlin will brook disappointment with regard to the transatlantic passage.

A number of the lines give no reduced rates, as the profession have been led to believe; others just in time to reach the Congress. Again, unless one takes the precaution to secure rooms some time before sailing, detention will occur in New York—due to the immense travel to Europe at this season of the year.

I presented a voucher from Dr. Atkinson to an agent here whose line offered rates only in July. After finding all outgoing ships full, I finally secured *at regular rates* the last unengaged and presumably the least desirable room on board. Although I was pleasantly and profitably detained more than a week in New York City, a similar detention might not suit others.

Yours truly,

E. J. Beall, M. D.

Fort Worth, Texas.

NOTES AND COMMENTS.

The Kola Nut.

An editorial note in the *Medical Press*, May 14, 1890, states that Professor Heckel, of Marseilles, has long made that peculiar African nut, the kola, a special study as regards its physiological effects. On April 8, he communicated the outcome of his experiments to the Académie de Médicine of Paris, through M. Rochard, who read the paper. The kola nut not only contains a small portion of caffeine—the active principle of tea, coffee and other similar drugs—but also several other alkaloidal bases. But these latter have not yet been so perfectly defined as has been the case with caffeine. M. Heckel has subjected the nut to an elaborate process of exhaustion with chloroform, whereby all the caffeine was extracted, and yet there remained a somewhat complex alkaloidal and tannic substance which proved very active. M. Heckel has separated this basis, and calls it "rouge de kola." Like the red basis of cinchona, this substance seems to have a powerful effect on the muscles. M. Heckel is strongly inclined to attribute the effects of the kola nut to this "rouge de kola," as he does not think the proportion of caffeine it contains sufficient to account for the marvellous results obtained; and, moreover, it must not be forgotten that these effects are still observed after all the caffeine has been carefully removed. M. Heckel has tried his experiments upon army men. On one occasion the colonel commanding the 106th Regiment, in garrison at Perpignan, took a small quantity of kola-nut powder (containing only about 0 gr. 12 of caffeine), and yet he was able to take a long walk, making the ascension of the Carrigon, a mountain of over 9,000 feet in height, all in twelve hours, with only twenty-five minutes' rest, and finished up his march in splendid style and without fatigue. Numerous other instances are on record where officers and men have performed arduous forced marches, without being in any way incommoded, upon a small pinch of kola-nut powder, such as would contain only about 0 gr. 15 of caffeine. The fresh nut, which is only chewed by the natives of Africa, also contains a rich oil; it is of an essential character, and is very active in exciting the nervous system. This essential oil, however, must be eliminated when the nut is used as an element of diet. It is in the form of a dry powder, or as a cake that M. Heckel has introduced it to the army and Alpine clubs. Many of the Alpine clubs, it is alleged, have generally adopted the kola nut as one of the principal items for a touring outfit, and find that they are thereby enabled to perform far more work with much less fatigue, and also escape all sensation of giddiness. M. Heckel is anxious that the kola nut should now be regularly adopted in the French army, not only for the men, but for the horses. He points out that the German military authorities are making experiments in this way. M. Colin and other members of the Académie de Médicine are, however, of opinion that caffeine is a much safer substance to work with, more especially as the active principles of the kola nut are but ill-defined, little known to any of them, and their action scarcely understood with sufficient accuracy.

Hereditary Transmission of Mutilation.

The question whether acquired mutilation in the parent can be transmitted to the child is one that often presents itself to the thoughtful biologist, and is one that perhaps would receive an affirmative answer from the majority of those who are accustomed to weigh the value of evidence. In most works on physiology in which the subject is mentioned at all, it is admitted that impressions made on the mother during pregnancy may affect the offspring, and cases are recorded where the father having a distorted finger from an injury, children were born with similarly distorted fingers; and others where accidental injury to an eye in one parent was followed by some defect of the same eye in the offspring. But when such cases are followed out, it will generally be found that they rest on hearsay, or that the facts have been observed or reported with little attention to the accuracy that is required to render them credible. Darwin, with his usual caution, remarks in his *Animals and Plants under Domestication*, that some mutilations have been practiced for a vast number of generations without any inherited result, and notes, with Godrou, that different races of man have from time immemorial knocked out their upper incisors, cut off joints of their fingers, made holes of immense size through the lobes of their ears

or through their nostrils, tattooed themselves, made deep gashes in various parts of their bodies, and yet that there is no reason to suppose that these mutilations have ever been inherited. Darwin refers, indeed, to the well-known experiments of Dr. Brown-Séquard, in which certain guinea-pigs transmitted epilepsy to their descendants after injury to the spinal cord; whilst others (after injury to the sciatic nerve, leading them to gnaw off their own toes) gave birth to toeless guinea-pigs; but after alluding to many other cases which have been recorded of cats, dogs and horses which have had their tails or legs amputated or injured, producing offspring with the same parts ill-formed, he remarks that as it is not very rare for such malformations to appear spontaneously, all such cases may be due to coincidence. Professor Weismann, in an essay on the supposed transmission of mutilations, expresses himself in much stronger terms. He points out that if mutilations must necessarily be transmitted, or even if they might occasionally be transmitted, a powerful support would be given to the Lamarckian principle, which is to the effect that a change in the structure of any part of an organism is chiefly brought about by exposure to new conditions of life which induces a change in habits; and this again leads to hypertrophy or atrophy of certain parts, and the modified parts are then transmitted to the offspring. On this principle Lamarck explained the long neck and the webbed feet of the swan, and the degeneration of the eyes in the proteus. Dr. Weismann refers to several frequently cited cases, and shows that they either rest on insufficient evidence or that their occurrence may be explained in other ways. Thus, in the case of the tailless breed of cats in the Isle of Man, there is no evidence to show when or how it commenced; indeed, it is probable that it is the outcome of a gradual process of reduction of the length of the tail, since a similar breed is found in Japan and preserved from an idea that such animals are better mousers; whilst the number of vertebræ that are suppressed may be as many as ten. He tells a good story showing the care that should be exercised in admitting the spontaneous origin of such anomalies. Last summer Professor Schottelius, of Freiburg, brought to Dr. Weismann a kitten with a congenital rudimentary tail, which he had accidentally discovered as one of a family of kittens at Waldkirch, a small town on the southern part of the Black Forest. The mother of the kitten possessed a perfectly normal tail; the father could not be identified. A closer investigation resulted in the following rather unexpected discovery. For some years past tailless kittens have frequently appeared in the families of many different mother cats at Waldkirch, and this fact is explained in the following manner. A clergyman who lived for some time at Waldkirch had married an English lady who possessed a tailless male Manx cat. The probability that all the tailless cats in Waldkirch are more or less distant descendants of that male cat almost amounts to certainty, and Dr. Weismann goes on to say since a male Manx cat has reached the Black Forest it might equally well arrive at some other place. In order to obtain experimental evidence on the point Dr. Weismann mutilated a number of white mice by cutting off their tails. As the families were successively born the tail of each member was cut off, until in the course of about fifteen months 901 young produced by five generations had been thus mutilated. Yet not only was there no instance of a tailless mouse being born, but in none was the tail shorter than 10.5 millimeters, the tail of a newly-born mouse varying normally from 10.5 to 12 millimeters in length. This result does not, indeed, prove that mutilations might not be inherited, but it does militate against the commonly accepted view that the mutilation of an individual is likely to be transmitted to the very next generation. The subject is one of much interest, and those who happen to meet with well-marked and well-authenticated instances of inheritance, if such cases ever occur, would do well to record them.—*Lancet*, March 15, 1890.

Oleoresin Peponis.

Louis Augustus Minner, Ph. G., in an inaugural essay, of which an abstract appears in the *Amer. Journal of Pharmacy*, June, 1890, describes a test of two samples of oil of pumpkin seed procured, one each from New York and Philadelphia. They were of a pale yellow color and became semi-solid at 32° F. One sample had considerable of a deposit resembling lard in color and consistency, and was rather freely soluble in alcohol. Both oils were administered for tænia, in the form of emulsion and in doses of half an ounce, followed by a dose of castor oil,

without expelling the tape-worm. He found, however, that the same quantity of the oleoresin of pumpkin seed promptly ejected large portions of the tænia.

For preparing this oleoresin the seeds were reduced to a coarse powder by triturating them in a mortar with pumice stone, exhausting with ether by maceration and percolation, and evaporating the solvent at a gentle heat. After washing the oil with some alcohol it formed a thick liquid of a red color, had a peculiar unpleasant odor and a disagreeable, rank taste. Its specific gravity at 60° F. is about 0.924. It is almost insoluble in alcohol, soluble in chloroform, ether, benzine and benzol, and does not congeal at 32° F. Strong sulphuric acid changes the color to green, then dark green, and after several hours to a dull red-brown, a blackish deposit being also formed. Strong nitric acid changes to red-brown, and after about five minutes causes violent effervescence, a disagreeable odor being given off, and, after cooling, a reddish-brown semi-solid mass is left.

Pumpkin seeds are not as frequently used as they would be if they could be administered in a more convenient form. The introduction of a reliable preparation seems desirable and, in Mr. Minner's opinion, the oleoresin is both a convenient and elegant as well as effective preparation. It can be easily and readily prepared, and is probably the most concentrated liquid form of pumpkin seed that can be devised. It may be given in doses of ½ to 1½ fluid ounce, in the form of an emulsion flavored with aromatics.

Pure Balsam of Peru not a Cause of Nephritis.

The possibility that the administration of balsam of Peru may result in nephritis has frequently been advanced as an argument against its continued use. Drs. Litten and V. Vamossy claim to have seen this unpleasant after-effect resulting from its use; and Nothnagel and Rossbach, in their work on therapeutics, distinctly state that the balsam of Peru, when given internally in large doses, is capable of producing gastro-intestinal catarrh, and inflammation of other mucous membranes. Landerer, and more recently still Drs. Bräutigam and Nowack, in the *Centralblatt für klin Med.*, No. 7, 1890, who have conclusively demonstrated that the continued use of the drug, in an emulsion in oil or in pill form and in large doses, is not followed by any nephritic or other inflammatory symptoms, although the resorption of the balsam was shown by the strongly acid reaction of the urine. Drs. Bräutigam and Nowack claim that the untoward effects of the balsam upon the kidneys, as noted by other observers, was probably due to an adulteration or impurity of the drug.—*Deutsche Med. Wochenschrift*, March 6, 1890.

Central Nervous System in Hydrophobia.

Professor N. M. Popoff, of Warsaw, has microscopically examined the brain and spinal cord from a fatal case of hydrophobia in a man bitten by a rabid dog, and found that nerve cells of the medulla oblongata and pons varolii undergo the most marked changes in the disease. The changes are identical with those described by Leyden and Erb under the name of "pigment atrophy" and by Charcot under that of "parenchymatous myelitis." The degeneration attacks almost all nerve cells in the said regions, but attains its maximal intensity in the nuclei of the cerebral nerves, affecting the motor nuclei by far less severely than the sensory ones.—*Vratch*, No. 14, 1890.

Suture of Both Tendons of Achilles.

At a meeting of the Allegheny County Medical Society, held Feb. 19, 1890, Dr. Buchanan reported a case of injury to one ankle joint, and to the leg on the opposite side, by a mowing machine. A man stepped in front of the cutting bar of a mowing machine and struck the horses; the animals responded immediately; the cutting bar of the machine cut off the tendo Achilles, passed directly through the ankle, cutting off both malleoli, both posterior arteries, and the tendon of the posterior tibial muscle. On the other side the section was higher up; it passed through the tendon of Achilles and cut a piece off the tibia. Both the tendons of Achilles were sewed with catgut—four stitches; the other stitches were put in place, and the usual antiseptic dressings applied without drainage. The man's wounds healed without any reaction or discharge whatever, and he walked well when the case was reported without support. The union of the tendons was perfect.

NEWS.

—The census enumerators have found in Philadelphia a woman 112 years old.

—Dr. Joseph W. Howe, of New York, died of apoplexy, June 7, on the Cunard Line steamer Umbria, on the way to Liverpool.

—The Hospital and Dispensary of St. Clement's Protestant Episcopal Church was opened in Philadelphia, June 16, with interesting services.

—A monument to the memory of Dr. Franz Anton Mesmer, from whom "mesmerism" derives its name, was unveiled at Dresden on May 26.

—A new university Poliklinik of Orthopædic Surgery was opened at Berlin on May 22. Dr. Julius Wolff has been appointed chief surgeon to the institution.

—It was reported, June 18, that yellow fever had broken out in Malaga, the germs of the disease having been brought in a cargo of cotton by a New Orleans steamer.

—Dr. Roger Keys died in Philadelphia, June 10, sixty-one years old. He was graduated at Albany Medical College in 1853. He was a well-known and public-spirited man.

—Dr. A. G. Walls, of Lock Haven, died suddenly at the Continental Hotel, Philadelphia, on June 16. Dr. Walls was graduated from the University of Vermont, Medical Department, in 1860.

—A brass tablet in memory of the late Miss Alice Fisher, originator and for years Chief Nurse of the Training School for Nurses at the Philadelphia Hospital, was unveiled June 16 at the Philadelphia Hospital.

—Annie F. Reynolds, the first woman dentist to graduate in Massachusetts, received her degree of D. D. S. from the Boston Dental College, June 19. She also received the first prize for senior honors.

—Dr. O. E. Ross, of Rockport, Maine, died recently at Sullivan's Island, Charleston, S. C., where he had gone for his health. Dr. Ross was graduated from the Berkshire Medical College, Pittsfield, Mass., in 1862.

—The will of Samuel Welsh, who died in Philadelphia, June 14, contains bequests of $50,000 each to the Trustees of the University of Pennsylvania and the Pennsylvania Hospital, and $25,000 to the Episcopal Hospital in this city.

—The new chapel in connection with St. Michael and All Angels' Home for Crippled Colored Children in Philadelphia, was consecrated June 18. It is the gift of Mrs. Bernard Henry in memory of her adopted daughter, Margaret Conner.

—Dr. Michael Lampen, a well-known physician of West Philadelphia, died suddenly June 18. He was born in 1831. He was graduated from the old Pennsylvania College in 1859. During the war he was a surgeon in the Satterlee Hospital, in West Philadelphia.

—A sub-agent of the State Board of Pharmacy is in jail in New York, on a charge of blackmail, and a warrant is out for the arrest of his superior, an agent for the Board of Pharmacy in New York city. They took "hush-money" from a non-registered pharmacist.

—Dr. Henry T. Child, a well-known and public-spirited citizen of Philadelphia, died in this city June 15, seventy-four years old. He was active as a temperance advocate and in the society for organizing charity, he also was very useful in aiding the Government during the War of the Rebellion.

—Dr. Lewis Rodman, a well-known physician of Philadelphia, died at his summer residence, Edgewater Park, N. J., June 20. He was born in Bucks county, in 1806; he studied medicine under the late Dr. Joseph Parrish, and was graduated from the medical department of the University of Pennsylvania in 1827.

—In two cases against Dr. Augustine Thompson, of Boston, who, it is alleged, fraudulently transferred several lots of property shortly after Mrs. Myra Beals had obtained a $40,000 verdict against him for alienating her husband's affections, Judge Allen in Supreme Court to-day decided for the plaintiff.

—Surgeon-General Hamilton, of the Marine Hospital Bureau, was informed, June 16, that a second case of yellow fever had developed on the British vessel Avon, now detained at the Chandleur Quarantine Station. He has also received a report from Merida, Yucatan, that twelve cases of yellow fever have occurred there and that there were fears of an epidemic.

—Dr. T. F. Berry, of Louisville, a graduate of the University of Louisville in 1890, and John Blankenbaker, a farmer living near Fisherville, Ky., went out to fight a duel, June 17, Dr. Berry being the challenger. When they were ready to fire the farmer stopped the duel on the ground that it would be an irreparable wrong if he should kill Berry, and he also had his own wife and children to remember.

SPECIAL OFFER

TO SUBSCRIBERS TO THE REPORTER WE MAKE THE FOLLOWING OFFER:

FOR TEN DOLLARS WE WILL SEND

The REPORTER for one year,	price alone,	$5.00
1 Model Ledger,		5.00
1 Accidents and Emergencies,		.75
1 Pocket Record for 1890,		1.25
	Total,	$12.00

FOR NINE DOLLARS WE WILL SEND

MEDICAL AND SURGICAL REPORTER,

P. O. BOX 843. PHILADELPHIA.

PIL. PHENACETINE ET SALOL, 5 GRS., "W. H. S. & CO."

{Phenacetine-Bayer, ... 2½ grs.}
{Salol, ... 2½ grs.}

Anti-Rheumatic and Analgesic. This combination was first suggested by Dr. M. F. Price, Colton, Cal., President of the "Southern California Medical Society." In an address to the members he says: "In a case of acute Rheumatism, affecting elbows, wrists, knees, and ankles, ordered Phenacetine and Salol every three hours. No local application ordered. Made five daily visits, found the patient each day improved, discharged with orders to continue the medicine three times a day for a week."

After citing other cases, one of Sciatica where the patient was suffering such pain that the slightest motion caused faintness with nausea and continuous vomiting; two with acute Rheumatism, and one with Neuralgia of the stomach, Dr. Price continues:

"It will be observed that in some of these cases I have combined Salol with Phenacetine. I did this on the principle of the well-known effect of Salicylic Acid in rheumatism, but I rely on the Phenacetine for the relief of the pain, and in this way perhaps the cure of the disease causing it." *Southern California Practitioner, August*, 1889.)

PIL. TERPIN HYDRAT., 2 GRS., "W. H. S. & CO."

A new and potent remedy in the treatment of coughs, catarrh, bronchitis and kindred diseases.

Terpin Hydrate is indicated in cases where violent irritation of the bronchial mucous membrane exists, and where the secretion is inconsiderable and peculiarly viscid, such as is met with in the chronic catarrh accompanying emphysema and phthisis. The effect obtained is always an increase and a liquefaction of the secretion, a considerable reduction of the irritation, and easy expectoration.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced in their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to maintain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

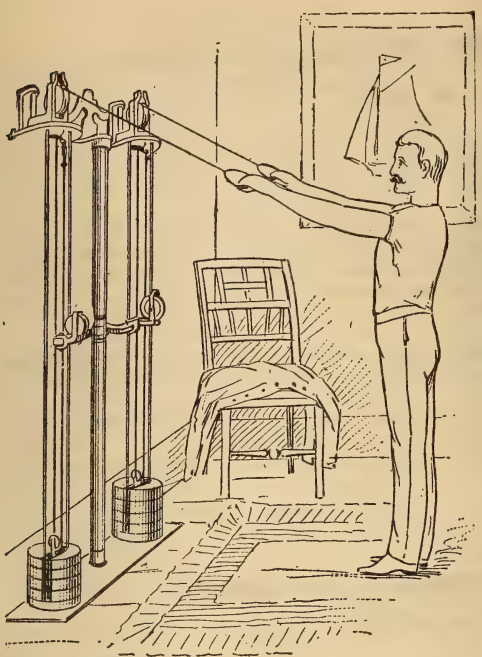
The continued favor which has been shown to our **Soluble Pills** is sufficient evidence that care has been bestowed upon their manufacture.

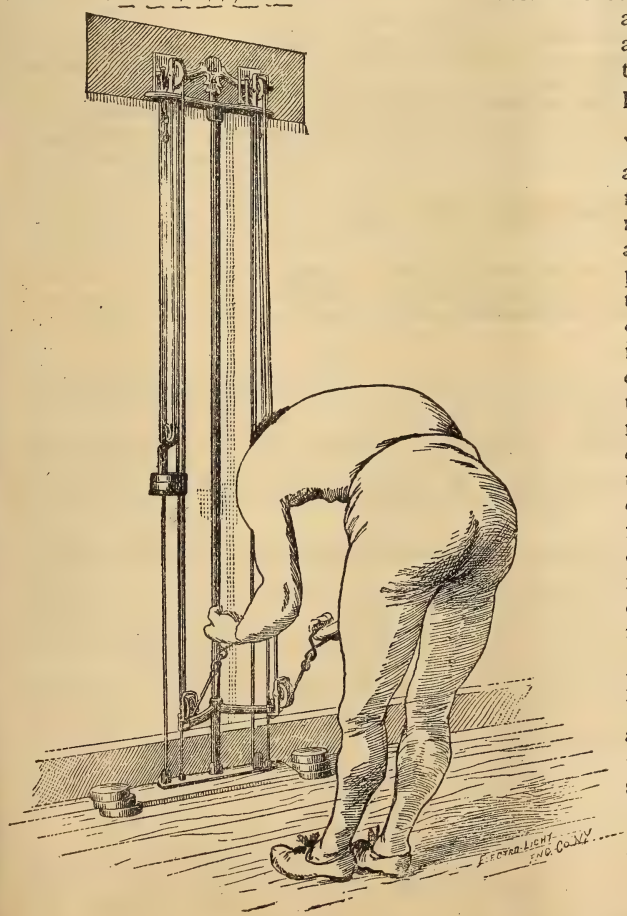
As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test, either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque, nor insoluble, but elastic, thin, transparent, and readily soluble.

For further information about them we refer to our formula books and price lists, which we shall be happy to furnish upon application.

W. H. Schieffelin & Co.,
170 & 172 William Street,
NEW YORK.





A. G. SPALDING & BROS.'

Gymnasium Department.

It has become a matter of record, that hereafter the **Gymnasium** in all its details will be one of the leading features of our business.

With the addition to our own valuable patents, those of the **A. J. Reach Company,** of Philadelphia, recently purchased by us, enables us to claim the most **extensive department** of **Gymnasium Appliances in the world.**

We have been encouraged in this **important** movement by the constantly increasing demand from **Colleges, Seminaries,** and other **Educational** Institutions for Gymnasium Supplies, and henceforth we shall devote special attention to furnishing **plans, specifications,** and **estimates** to such and for **private residences** as well, and solicit correspondence with all contemplating the introduction of gymnastics for any purpose.

The Peerless and Pulley Weight, illustration of which appears on this page, is a most perfect appliance for the development of the **chest** and **arms,** adjustable to the height of *any* person, and in weight from five to thirty pounds, for home exercise. For **man or woman** this is the peer of any method yet devised. Realizing the attention the **clergy** and the **teacher** are now giving to **healthful** exercise in **schools,** we solicit also their correspondence, and any orders or business proceeding from such will be gratefully received and entitled to our best rates of discount, and will receive prompt and careful attention.

Visitors to our different establishments at **Chicago, New York,** and **Philadelphia** will always be welcome and politely served by the many efficient salesmen constantly in attendance. **A. G. SPALDING & BROS.,**

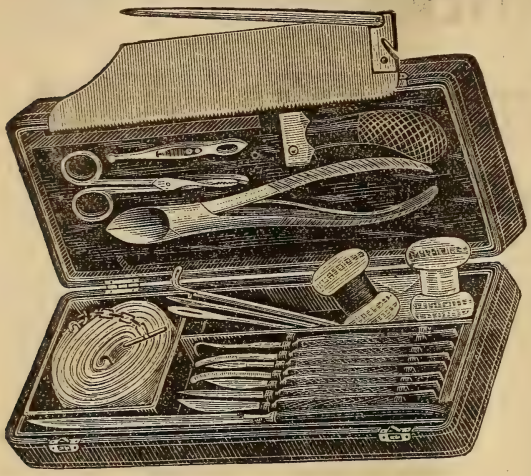
108 Madison St. 241 & 243 Broadway.
PHILADELPHIA, **1022 Market St.**
LONDON, ENGLAND, **38 Holborn Viaduct.**

LENTZ'S ASEPTIC COMPACT OPERATING SET, No. 10.



We have from time to time made improvements to this set and are now making a perfect aseptic set, which offers especial facilities for aseptic precautions; the blades are soldered into hollow German-silver handles, nickel-plated, are light so as not to be unwieldy and admit of a firm grasp when operating.

The saw is adjusted to the handle on an entirely new principle, being made to separate easily and to facilitate thorough cleansing.

The handle is entirely of metal and fenestrated to overcome unnecessary weight.

Scissors and Forceps having French locks can be separated, and the slide can be easily removed from Artery and Needle Forceps.

Therefore, no opportunity is offered for the lodgment and development of germs.

The entire set is patterned with especial reference to facility in cleansing.

The instruments can be sterilized by placing them in boiling water, without fear of damaging them. Wood or rubber handles will not admit of this procedure. For price, see case A.

The following instruments are put up in either a fine Mahogany or Morocco case, with nickel trimmings, lined with velvet, and has an extra space for Trephine with handle, and Elevator if desired.

One Amputating Knife (6 in. blade); One Finger Knife; One Hernia Knife; One Sharp Curved Bistoury; Two Scalpels; One Tenotome; One Tenaculum; One Pair Scissors, curved or flat; One Saw (9 in. blade); One Liston's Bone Forceps, with Spring; One Artery and Needle Forceps, improved; One Esmarch's Flat Rubber Tourniquet, with Chain; One Hæmostatic Forceps; One Director, with Aneurism Needle; Two Silver Probes; Silk, Wire, Wax and Needles.

With the Sixteen Instruments Contained in this Case, any Ordinary Operation may be Performed.

SIZE, 11 INCHES LONG, 4 INCHES WIDE, 2 INCHES HIGH.

A.—German Silver aseptic Handles on Knives and Saw, ... **$34 00**
B.—Hard Rubber aseptic Handles on Knives and Saw, ... **29 00**
C.—Ebony Handles on Knives and Saw (as shown in illustration), ... **25 00**
Either Set, with Trephine and Elevator in addition, ... **4 65**

DISCCUNT 25 PER CENT. TO PHYSICIANS. Our Catalogue of 260 pages will be sent on receipt of 10 cts. for postage

CHARLES LENTZ & SONS, Manufacturers of Surgical and Orthopædic Apparatus,

Established 1866. **18 North Eleventh Street, Philadelphia.**

The Acutely Ill.

When a patient is acutely ill, the digestive powers share in the general condition, and consequently the food supplied should be of the most easily assimilable character. The predigestion of starchy matters outside the body, as in MELLIN'S FOOD, is necessary, and the soluble carbohydrates of which this food consists, soluble because predigested, form the true food of the acutely ill.—J. MILNER FOTHERGILL, M.D., Edin.

A sample of MELLIN'S FOOD *will be sent to any physician, free of expense, upon application.*

Doliber-Goodale Co., Boston, Mass.

GARDNER'S

SYRUP OF HYDRIODIC ACID,

Introduced in 1878 by R. W. GARDNER.

The Reputation which Hydriodic Acid has Attained During the past Eleven Years was Won by this Preparation.

Numerous Imitations prepared differently, and weaker in Iodine, are offered, from the use of which the same therapeutic effects cannot be obtained.

Caution.—Use no Syrup of Hydriodic Acid which has turned red. This shows decomposition and free Iodine. In this state it acts as an irritant and fails to produce desirable results.

Unprincipled apothecaries substitute imitations when Gardner's Syrup is prescribed, and physicians, failing to get desirable and promised results, attribute the fault, unjustly, to Gardner's Syrup.

THERAPEUTIC INDICATIONS.

Hay Fever; Rose Cold; Poisoning by Lead, Mercury or Arsenic; Acute and Chronic Rheumatism; Asthma; Chronic Bronchitis; Catarrh; Congestion of Lungs in Children; Adenitis; Eczema; Lupus; Chronic Malarial Poisoning; Lumbago; Acute Pneumonia; Psoriasis; Scrofulous Diseases; Goitre; Enlarged Glands; Cold Abscesses; Indolent Sores; Excessive Fat; Fatty Degeneration of the Heart; to absorb non-malignant Tumors; and in the latter stages of Syphilis; Syphilitic Phthisis.

Details of treatment furnished physicians upon application to undersigned without charge.

Gardner's Chemically Pure Syrups of Hypophosphites.

Embracing the separate Syrups of Lime, of Soda, of Iron, of Potassa, of Manganese, and an Elixir of the Quinia Salt; enabling physicians to accurately follow Dr. Churchill's method, by which thousands of authenticated cases of Phthisis have been cured The only salts, however, used by Churchill in Phthisis are those of Lime, of Soda, and of Quinia, and always separately according to indications,—never combined.

The reason for the use of single Salts is because of antagonistic action of the different bases, injurious and pathological action of Iron, Potassa, Manganese, etc., in this disease.

These facts have been demonstrated by thirty years' clinical experience in the treatment of this disease exclusively, by Dr. Churchill, who was the first to apply these remedies in Medical practice. Modified doses are also required in this disease; seven grains during twenty-four hours being the maximum dose in cases of Phthisis, because of increased susceptibility of the patient to their action, the danger of producing toxic symptoms (as hemorrhage, rapid softening of tubercular deposit, etc.), and the necessity that time be allowed the various functions to recuperate simultaneously; over-stimulation, by pushing the remedy, resulting in crisis and disaster.

A pamphlet of sixty-four pages, devoted to a full explanation of these details and others, such as contra-indicated remedies, indications for the use of each hypophosphite, reasons for the use of absolutely pure Salts, protected in Syrup from oxidation, etc., mailed to physicians without charge upon application to

R. W. GARDNER, 158 William St., N. Y. City.

RABUTEAU'S DRAGEES OF IRON

Laureate of the Institute of France.—Prize in Therapeutics.

The studies made by the Physicians of the Hospitals have demonstrated that the **Genuine Dragees of Iron of Rabuteau** are superior to all other preparations of Iron in cases of *Chlorosis, Anæmia, Leucorrhœa, Debility, Exhaustion, Convalescence, Weakness of Children*, and the maladies caused by the Impoverishment and Alteration of the blood after periods of fatigue, watching, and excesses of any kind.

TAKE 4 TO 6 DRAGEES DAILY.

Rabuteau's Elixir of Iron is recommended to those persons who may be unable to swallow the Dragees. Dose —*A small wineglassful with meals.*

Rabuteau's Syrup of Iron is specially designed for children. Chalybeate medication, by means of **Rabuteau's Iron**, is the most economical and the most rational known to therapeutics.

No constipation, no diarrhœa, complete assimilation.

Take only the GENUINE IRON OF RABUTEAU of

CLIN & CO., Paris.

SOLUTION OF

THE SALICYLATE OF SODA OF DOCTOR CLIN.

Laureate of the Paris Faculty of Medicine (MONTYON PRIZE).

Dr. Clin's Solution, always identical in its composition, and of an agreeable taste, permits the easy administration of *pure Salicylate of Soda*, and the variation of the dose in accordance with the indications presented.

"The *Salicylate of Soda* used by **Clin** is of perfect purity, "and is prepared with the greatest care; it is a medicament "in which we may have every confidence."

—*Paris Society of Medicine, Meeting of Feb. 8th, 1879.*

Clin's Solution, very exactly mixed, contains: 2 grammes of *Salicylate of Soda* per tablespoonful, 50 centigrammes of *Salicylate of Soda* per teaspoonful.

Paris—CLIN & CO.—Paris

NEURALGIAS

PILLS OF DR. MOUSSETTE.

The **Moussette Pills** of aconitine and quinium, calm or cure *Gastralgia, Hemicrania, Headache, Sciatica*, and the most obstinate Neuralgias.

"The sedative action exerted by the **Moussette Pills** "upon the apparatus of the sanguineous circulation by the "intermediation of the vaso-motor nerves, indicates their "use in *neuralgias of the trigemini nerves*, (fifth pair), *con-* "*gestive neuralgias*, and *painful and inflammatory Rheumatismal* "*affections*."

"Aconitine produces marvelous effects in the treatment "of *facial neuralgias* when they are not symptomatic of "intracranial tumor."—*Society of Biology of Paris, Meeting* "*of the 28th February, 1880.*

DOSE—Take 3 to 6 pills during the twenty-four hours.

ACCEPT ONLY THE GENUINE MOUSSETTE PILLS OF

CLIN & CO.,—Paris.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the **three** Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PARIS.—22 RUE DROUOT.—PARIS.

The 153d Semi-Annual Course of Instruction on Practical Obstetrics, at the Phila. Lying-in Charity's School of Practical Obstetrics Began Monday Oct. 7th, 1889.

The course of Instruction will embrace the same features that have made it so popular in the last few years. There is an abundance of material, and every Student will receive Instruction at the bedside of the LIVING WOMAN, in ACTIVE labor. For application for membership in the class (which is limited) apply to Dr. Charles Meigs Wilson, Surgeon in charge, Phila. Lying-in Charity, S. W. Cor. 11th & Cherry Sts., Phila.

A limited number of advanced or post-graduate Students will be taken for Instruction on Practical Gynecology. All hours will be arranged so as not to interfere with the work at the various Colleges. The Instruction and opportunities of the Lying-in Charity are free to Dr. Wilson's Office Students.

ONEITA

The perfection of table waters, with mineral properties unsurpassed in the treatment of Dyspepsia, Kidney and Liver troubles, Gout, Rheumatism, etc. The analysis of the spring shows a combination of mineral virtues unequaled in any other water. The water has been before the public but a short time, yet in that time has won public favor to a marked degree. Send for analysis of C. F. Chandler, Ph. D.

ONEITA SPRING CO.,
UTICA, N. Y.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhœa, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

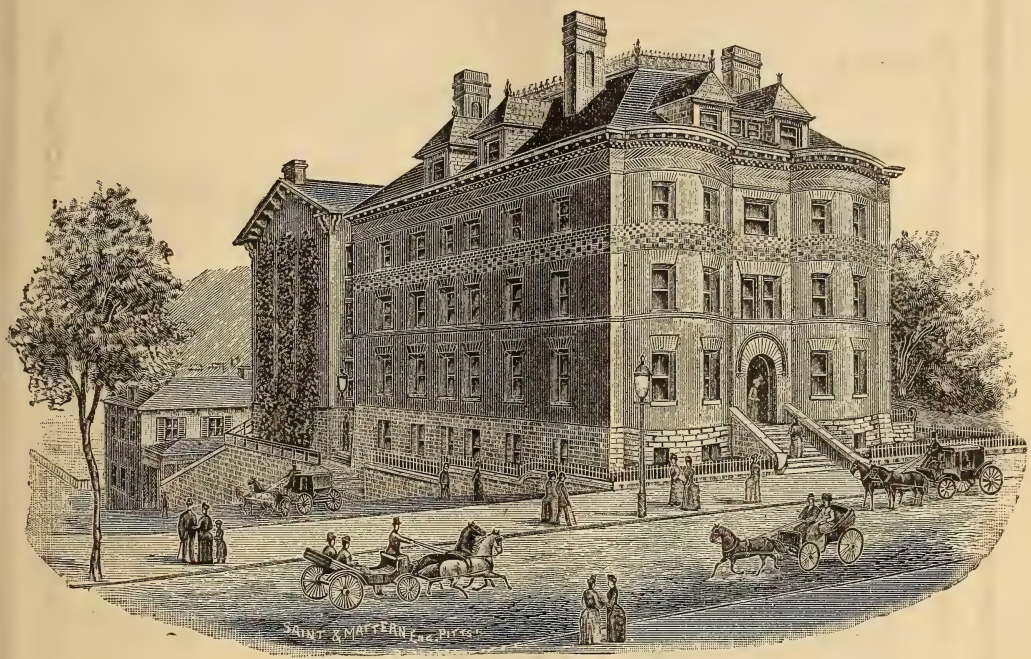
DR. R. S. SUTTON'S

Sanatorium for Diseases of Women.



Seventh Year Opens September 1, 1889.

ALLEGHENY CITY, PA.

This Institution is located on high ground, and overlooks the Allegheny, Monongahela and Ohio rivers; it commands a view of the city of Pittsburgh, and its picturesque surroundings. The building is large and beautiful, it is provided with every modern convenience, the halls are heated by steam, the rooms are commodious, well lighted and ventilated, and heated by open grates. The house is provided with a private parlor and reading-room for patients. The dining-room is large, handsomely finished, and furnished with small tables, securing privacy at meals for those who do not care to have meals served in their own rooms. Patients can be as secluded, should they desire it, as in a well appointed hotel. Each patient is examined by Dr. Sutton, and receives his daily personal attention, while Dr. J. H. Williamson, a physician of ample hospital experience, resides in the Institution, and has, under Dr. Sutton, the immediate care of the patients. The Institution accommodates 25 patients, and is equal in comfort to the best hotels.

Electricity, baths, douches, massage, local treatment, general medication and surgical operations are resorted to according to the requirements of each patient.

For further information address the Matron

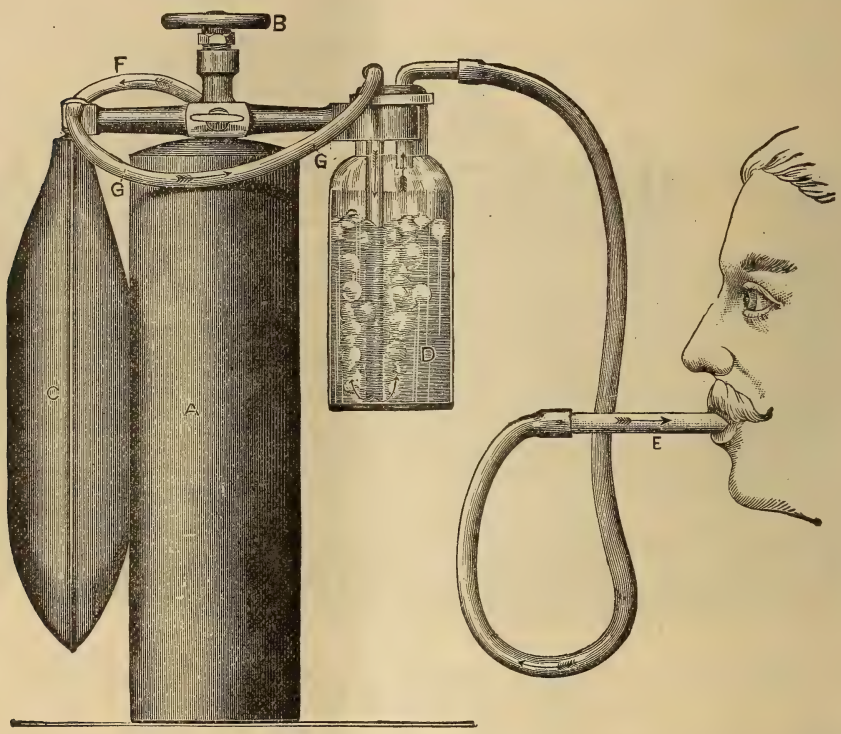
INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.
LAMBERT'S
LITHIATED HYDRANGEA
KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request.

LAMBERT PHARMACAL CO., ST. LOUIS, MO.

CALIFORNIA VINTAGE CO.
21 PARK PLACE N.Y.

Geo Hamlin Prest. Chas Roome Parmele Treas.

GENTLEMEN:

The Case of your wines sent me for analysis by Dr. A. L. Hummel, of the "Annals of Hygiene," containing specimens of your La Rosa Zinfandel, Mataro, Riesling, Royal Tokay, and Royal Grape Brandy, has been duly received.

I have examined them for the common contaminants of wine; to wit: Sulphurous acid and sulphites, salicylic acid, fuchsin, lead salts, etc., none of which I found present therein.

I have also determined their alcoholic strength, extractives, and ashes, and found them to correspond strictly in this respect with the standard of pure and natural wines, which cannot be said of many of the imported wines.

As a native of a wine-producing country, I consider myself somewhat of a judge of wines, and regard your products as comparing more than favorably with most of the wines from abroad which are sold at higher prices, so much so that I enclose within my order for fifty bottles of La Rosa Zinfandel, which I expect to use hereafter exclusively at my table.

Very Respectfully,

L. WOLFF, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

Permanent Pepsin.

THE INSEPARABLE STANDARDS OF VALUE ARE PERMANENCY AND ACTIVITY.

WHEN a physician prescribes pepsin and his patient finds that it "sticks to the paper," that it forms a gummy mass "in powders," he may rely upon it that FAIRCHILD'S PEPSIN has not been dispensed; if he has ordered Fairchild's, this behavior is positive evidence that he and his patient have been the victims of "substitution."

Pepsins which are hygroscopic, which do undergo upon exposure to air the changes characteristic of peptone, are offered (in the form of scales and in powder) with pretensions to permanent quality.

If a product is sought, of well-proven permanency and of highest standard of activity, FAIRCHILD'S PEPSIN is the one which will never give cause for complaint.

Fairchild's was the original "Scale Pepsin;" the first positively "free from starch, sugar, acid, peptones or any added substance." The host of imitations of "Scale Pepsin" bear witness to the value and reputation of the original.

FAIRCHILD BROS. & FOSTER,

82 and 84 Fulton Street, New York.

A Phosphorized Cerebro-Spinant

(FRELIGH'S TONIC).

FORMULA.

Ten minims of the Tonic contain the equivalents (according to the formulæ of the U. S. P., and Dispensatory) of

Tinct. Nux Strychnos,	1 minim.
" Ignatia Amara,	1 "
" Cinchona,	4 "
" Matricaria,	1 "
" Gentian,	½ "
" Columbo,	½ "
" Phosphorus, C. P.,	1-300 gr.
Aromatics,	2 minims.

Dose: 5 to 10 drops in 2 tablespoonfuls of water.

INDICATIONS.

Paralysis, Neurasthenia, Sick and Nervous Headache, Dyspepsia, Epilepsy, Locomotor Ataxia, Insomnia, Debility of Old Age, and in the Treatment of Mental and Nervous Diseases.

A BALTIMORE PHYSICIAN, WHOSE DIPLOMA DATES FROM 1825, SAYS:

"Your combination I find vastly more effective than any tonic I have ever used. It furnishes a most powerful evidence of the vastly increased power of medicament by combination and judicious pharmaceutic preparation."

Price, One Dollar per Bottle, containing 100 of the Average 5-Drop Doses.—Physicians' single sample delivered, charges prepaid, on application. That every physician may be his own judge of its value, irrespective of the opinions of others, we make the following

SPECIAL OFFER:

We will send to any physician, delivered, charges prepaid, on receipt of twenty-five cents, and his card or letter-head, half a dozen physicians' samples, sufficient to test it on as many cases for a week to ten days each. The Tonic is kept in stock regularly by all the leading wholesale druggists of the country. As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-lists, etc., address,

I. O. WOODRUFF & CO.,

Manufacturers of Physicians' Specialties,

Apollinaris

"THE QUEEN OF TABLE WATERS."

The filling at the Apollinaris Spring (Rhenish Prussia), amounted to

11,894 000 BOTTLES IN **1887,**
12,720.000 BOTTLES IN **1888,** AND
15,822,000 BOTTLES IN **1889.**

"The annual consumption of this favorite beverage affords a striking proof of the widespread demand which exists for table water of absolute purity, and it is satisfactory to find that, wherever one travels, in either hemisphere, it is to be met with; it is ubiquitous, and should be known as the cosmopolitan table water. 'Quod ab omnibus, quod ubique.'"—BRITISH MEDICAL JOURNAL.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

THE VALUE OF NUTRITION IN DISEASE.

All physicians who have ever used Murdock's Liquid Food and Suppositories recognize their value over all other foods, in breaking up disease and building up the patients after disease, preventing a relapse, **as the same results are obtained as in surgery.** Its value in surgical cases we illustrate by the records of the different cities and of Murdock's Free Surgical Hospital for Women, which is the largest in the United States. It contains 114 beds, every bed free, including operation, the operations ranging from 1000 to 1200 yearly, representing 90 of the worst classes known in surgery. Among these cases we have had **Cancer of uterus** (*Kolpo-hysterectomy*), 13; **Salpingitis** (*Tait's operation*), 31; **Fibroid of uterus** (*abdominal hysterectomy*), 19; **Ventral operation, hernia,** (*abdominal section*), 12; **Cancer of bowel** (*incision*), 2; **Parovarian cyst, 6; Papillomatous cyst** (*extirpation*), 4; **Tubercular peritonitis** (*incision*), 1, **Ovarian cystoma 27; Nymphomania** (*Battey*), 1; **Exploratory abdominal incisions, 12; Fibroid with abdominal abscess** (*Hegar*), 2; **Hysterorraphy, 2; Dermoid cyst, 3; Cirrhotic ovaries,** (*Battey*), 4; **Fibroid uterus** (*Hegar*), 6; **Hystero-epilepsy** (*Battey*), 1; **Haemato-Salpinx** (*Tait*), 5; **Rupture of intestine into vagina, 1; Dislocated kidney, 2; Fibroid tumor abdominal wall, 1; Resection of intestine** (*Senn*), 1; **Ruptured perineum, 294.** Patients are in the Hospital 8 days before and 26 days after operation, on an average.

In Boston, last year, 42 deaths were from Cancer in the Breast. In Murdock's Hospital, 35 such cases were operated on without a death, the patients remaining in the Hospital, on an average, 18 days.

Mortality in Boston,	25.60	per	1000.
" of Women in Boston,	29,00	"	"
" in **Murdock's Free Surgical Hospital,**	**5.00**	"	"
" New York,	26.32	"	"
" Philadelphia,	20.00	"	"
" Chicago,	20 90	"	"
" St. Louis,	20.49	"	"

showing our mortality is only one-sixth as great as of those in health. As good results were obtained in our General Hospital, which we kept open 27 months, **thus showing the value of nutrition as found in Murdock's Liquid Food, and so recognized by the British and American Medical Associations,** before which essays were read and discussed, and it is the only Raw food preparation on which essays were ever read.

Physicians are invited to visit our Hospitals and Works, also to send in patients and to be present at the operations. For any physician who has not used our Liquid Food (and Suppositories for adults and infants), we will deliver free samples to any express company in Boston.

When babies do not thrive, never change their food, but add five or more drops at each feeding of Murdock's Liquid Food, and their lost or needed vitality will be restored in less than thirty days. It is invaluable when weaning babies or when teething. If mothers will take one teaspoonful to a tablespoonful before each meal and on retiring, they will receive as much benefit as the baby.

Murdock Liquid Food Co., Boston.

CELERINA

NERVE TONIC, STIMULANT AND ANTISPASMODIC.

FORMULA.—Every Fluid Drachm represents FIVE grains EACH—Celery, Coca, Kola, Viburnum and Aromatics.

INDICATIONS.—Loss of Nerve-Power (so usual with Lawyers, Preachers, Writers and Business Men), Impotency, Spermatorrhea, Nervous Headache, Neuralgia, Paralysis, Hysteria, Opium Habit, Inebriety, Dyspepsia, and ALL LANGUID conditions of the System.

Indispensable to restore a patient after alcoholic excess.

DOSE.—One or two Teaspoonfuls three or more times a day, as directed by the Physician.

LIQUID IRON-RIO

Palatable and easily assimilated. Does not produce Nausea, nor irritate the Stomach. Does not Cause Headache, nor Constipate. Does not Stain the Teeth. It is so Acceptable to the Stomach that its Use is Admissible when all other forms of Iron would be rejected. Being so Readily Assimilable, it only requires a small Dose.

Each Fluid Drachm contains ONE GRAIN of Iron in a Pleasant and Digestible Form.

DOSE.—One or more Teaspoonfuls as indicated, during or after meals.

S. H. KENNEDY'S

CONCENTRATED EXTRACT OF

PINUS CANADENSIS

DARK. A NON-ALCOHOLIC LIQUID. WHITE.

A MOST VALUABLE NON-IRRITATING MUCOUS ASTRINGENT.

INDICATIONS.—Albuminuria, Diarrhea, Dysentery, Night-Sweats, Hemorrhages, Profuse Expectoration, Catarrh, Sore Throat, Leucorrhea, and other Vaginal Diseases, Piles, Sores, Ulcers, Burns, Scalds, Gonorrhea, Gleet, Etc.

When Used as an Injection, to Avoid Staining of Linen, the WHITE Pinus should be used.

RECOMMENDED BY PROMINENT EUROPEAN AND AMERICAN PHYSICIANS.

RIO CHEMICAL CO., St. Louis, Mo., U. S. A.

LONDON. PARIS. CALCUTTA. MONTREAL.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

Sole Agents for the above Preparations.

Doctor, we offer You a complete solution of the Question of Infant Feeding.

It is universally conceded that Mother's Milk of good quality is the best nutriment for infants.

This is the nourishment that we enable nursing mothers to supply abundantly.

When our new preparation, **NUTROLACTIS**, is given to nursing mothers whose milk is scanty, although the breasts are almost entirely dry, it will in the course of two days, or three at farthest, so increase the quantity that there will be milk enough to completely nourish a vigorous infant; the quality of the milk will be good, and at the same time the health and strength of the mother will be improved.

If the quantity of a mother's milk be adequate but the quality poor, lacking in nutritive elements, the use of this remedy will quickly and notably improve the quality and maintain the quantity until the end of normal lactation.

Physicians are assured that its use is always perfectly harmless.

Formula, Galega officinalis, G. Apolinea, G. Tephrosia. See Sillé & Maisch's National Dispensatory.

PREPARED BY

The Roseberry Nutrolactis Company,

ESTABLISHED 1855.

DRS. STRONG'S SANITARIUM,

SARATOGA SPRINGS, NEW YORK,

Receives persons recommended to it by their home physicians for Treatment, Change, Rest or Recreation, and places them under well-regulated hygienic conditions so helpful in the treatment of chronic invalids or the overtaxed.

For Treatment: In addition to the ordinary remedial agents, it employs Turkish, Russian, Roman, Sulphur, Electro-Thermal, the French Douche (Charcot's), and all Hydropathic Baths; Vacuum Treatment, Swedish Movements Massage, Pneumatic Cabinet, Inhalations of Medicated, Compressed, and Rarefied Air, Electricity in various forms, Thermo-Cautery, Calisthenics, and Saratoga Waters, under the direction of a staff of educated physicians.

For Change: This Institution is located in a phenomenally dry, tonic, and quiet atmosphere, in the lower arc of the Adirondack Zone, and within the "Snow Belt."

For Rest: The Institution offers a well-regulated, quiet home, heated by steam and thoroughly ventilated, with cheering influences and avoiding the depressing atmosphere of invalidism.

For Recreation: To prevent introspection, are household sports at all seasons of the year, and in Winter, tobogganning, elegant sleighing etc.; in Summer, croquet, lawn-tennis, etc.

Private professional references furnished upon application. Physicians are invited to inspect the Institution at their convenience. A liberal discount to physicians and their families.

For further information, address,

DRS. S. S. & S. E. STRONG.

THE OLD STYLE discarded on account of pulling apart, while the elastic is still in good condition.

THE "MASTER" SURGICAL ELASTIC STOCKINGS

FOR VARICOSE VEINS, WEAK AND SWOLLEN JOINTS, DROPSY OF THE LIMBS, SPRAINS, etc.

PROVIDED WITH

THE PATENT NON-ELASTIC STAYS AND ADJUSTING LOOPS,

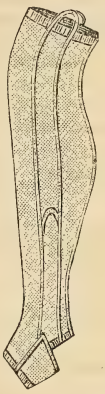
By the aid of which they can be drawn on easily, like pulling on a boot. They will last much longer than the old style, as the stays prevent them from being torn apart in drawing them on.

ALL KINDS AND SIZES IN THREAD OR SILK ELASTIC. Made under D. Master's Patents, Nov. 29, 1881, March 21, 1882. Send for descriptive circular and price-list to

POMEROY TRUSS CO.,

785 Broadway, New York.

DANIEL POMEROY, Pres. CHARLES R. DEAN, Sec.



THE NEW STYLE cannot pull apart and consequently lasts until worn out.

NOW READY FOR DISTRIBUTION.

NEW CATALOGUE. SIXTH EDITION.

SURGICAL INSTRUMENTS.

464 Pages. 4,000 Illustrations.

Full Bound, 50 cents. Plain, 20 cents. Charge for Transportation and Binding only.

JOHN REYNDERS & CO.,

UNIVERSITY OF PENNSYLVANIA.—Medical Department.

The 124TH ANNUAL WINTER SESSION began Tuesday, October 1st, 1889, at 12 M., and will continue until May 1st, 1890.
The PRELIMINARY SESSION began September 18th, 1889.
The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology, with Bedside Instruction in Medicine, Surgery and Gynecology are a part of the regular course and without additional expense.

FACULTY.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
D. HAYES AGNEW, M.D., LL.D., Honorary Professor of Clinical Surgery.
WILLIAM PEPPER, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
WILLIAM GOODELL, M.D., Professor of Gynecology.
JAMES TYSON, M.D., Professor of Clinical Medicine.
HORATIO C. WOOD, M.D., LL.D., Professor of Materia Medica, Pharmacy and General Therapeutics.
THEODORE G. WORMLEY, M.D., LL.D., Professor of Chemistry and Toxicology.
JOHN ASHHURST, JR., M.D., Professor of Surgery and of Clinical Surgery.
EDWARD T. REICHERT, M.D., Professor of Physiology.
WILLIAM F. NORRIS, M.D., Honorary Prof. of Ophthalmology
BARTON COOKE HIRST, M.D., Professor of Obstetrics.
J. WILLIAM WHITE, M.D., Professor of Clinical Surgery.
JOHN GUITÉRAS M.D., Professor of General Pathology and Morbid Anatomy.
GEORGE A. PIERSOL, M.D., Professor of Histology and Embryology.
SAMUEL G. DIXON, M.D., Professor of Hygiene.

For Catalogue and announcement containing particulars, apply to
DR. JAMES TYSON, Dean,
36th and Woodland Avenue, Philadelphia.

WESTERN PENNSYLVANIA MEDICAL COLLEGE
CITY OF PITTSBURGH.
SESSIONS OF 1889—90.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.
The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. J. W. J. McKENNAN.
Business correspondence should be addressed to
PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

NATIONAL MEDICAL COLLEGE.
MEDICAL DEPARTMENT OF THE
COLUMBIAN UNIVERSITY,
WASHINGTON, D. C.

The 68th Annual Session will begin October 7th and end March 1st. Graded three years' course required. Women admitted. Professors: J. F. Thompson, W. W. Johnston, A. F. A. King, E. T. Fristoe, Wm. Lee, D. W. Prentiss, D. K. Shute.

For circulars, address
A. F. A. KING, M. D., DEAN, 726 THIRTEENTH ST., N. W., WASHINGTON D. C.

DETROIT COLLEGE OF MEDICINE.
SESSION 889-90.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.
REGULAR SESSION opens on Wednesday, Sept. 25, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.
SPRING SESSION begins April 2d, 1890; and closes June 11th.
FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.
For further particulars, and for College Circular, apply to

THE NEW YORK POLYCLINIC is a School of Clinical Medicine and Surgery for *Practitioners only*. No didactic lectures are given The classes are limited. The demonstrations are made at the Polyclinic School and Hospital, and in the various Hospitals in New York City with which the Faculty are connected.

Session of 1889–90 opens Monday, September 16th, 1889. For further information and for catalogue, address

JOHN A. WYETH, M. D.,
Secretary of the Faculty,

Or WILLIS O. DAVIS, Clerk,
214, 216 & 218 East 34th Street, New York City.

The only prominent Emulsion of Cod-Liver Oil introduced directly to the medical profession. It is advertised exclusively in medical journals.

HYDROLEINE.

(HYDRATED OIL.)

Produces rapid increase in Flesh and Strength.

FORMULA.—Each Dose contains:			
Pure Cod Liver Oil.....30 m. (drops)		Soda.....1-3 Grains.	
Distilled Water.....35 "		Salicylic Acid.....1-4 "	
Soluble Pancreatin..... 5 Grains.		Hyocholic Acid.....1-30 "	

Recommended and Prescribed by EMINENT PHYSICIANS Everywhere. It is pleasant to the Taste and acceptable to the most delicate Stomach.

IT IS ECONOMICAL IN USE AND CERTAIN IN RESULTS.

HYDROLEINE (Hydrated Oil) is not a simple alkaline emulsion of oleum morrhuæ, but a hydro-pancreated preparation, containing acids and a small percentage of soda. Pancreatin is the digestive principle of fatty foods, and in the soluble form here used, readily converts the oleaginous material into assimilable matter, a change so necessary to the reparative process in all wasting diseases.

The following are some of the diseases in which **HYDROLEINE** is indicated:,

Phthisis, Tuberculosis, Catarrh, Cough, Scrofula, Chlorosis, General Debility, etc.

TO BRAIN WORKERS of all classes, **HYDROLEINE** is invaluable, supplying as it does, the true brain-food, and being more easily assimilated by the digestive organs than any other emulsion.

The principles upon which this discovery is based have been described in a treatise on "The Digestion and Assimilation of Fats in the Human Body," and "Consumption and Wasting Diseases," by two distinguished London physicians, which will be sent free on application.

SOLD BY DRUGGISTS GENERALLY.

C. N. CRITTENTON,

SOLE AGENT FOR THE UNITED STATES. **115 FULTON STREET, N. Y.**

A Sample of Hydroleine will be sent free upon application, to any physician (enclosing business card) in the U. S.

WE ARE CONFIDENT THAT WE HAVE REACHED THE **Highest Degree of Perfection** *IN SOLVING THE* **INFANT FOOD PROBLEM.**

Lacto-Preparata.

A Prepared Human Milk perfectly Sterilized and especially designed for Children from birth to six or eight months of age.

Made wholly from cow's milk with the exception that the fat of the milk is partially replaced by cocoa butter. Cocoa butter is identical with milk fat in food value and digestibility, being deficient only in the principle which causes rancidity. The milk in *Lacto-Preparata* is treated with Extract of Pancreas at a temperature of 105 degrees, a sufficient length of time to render twenty-five per cent. of the casein soluble, and partially prepare the fat for assimilation. In this process the remaining portion of the casein not peptonized, is acted upon by the pancreatic ferment in such a manner as to destroy its tough tenacious character, so that it will coagulate in light and flocculent curds, like the casein in human milk.

Lacto-Preparata is not designed to replace our **Soluble Food,** but is better adapted for Infants up to eight months of age.

Carnrick's Soluble Food

Is the Nearest Approach to Human Milk that has thus far been produced, with the exception of Lacto-Preparata.

During the past season a large number of Physicians and eminent Chemists visited our Laboratory at Goshen, N. Y., and witnessed every detail connected with the production of Carnrick's Soluble Food. This invitation to witness our process is continuously open to Physicians and Chemists. All expenses from New York to Goshen and return will be paid by us. The care used in gathering the milk, its sterilization, and the cleanliness exercised in every step, cannot be excelled. Soluble Food has been improved by increasing the quantity of milk sugar and partially replacing the milk fat with cocoa butter.

SULPHO-CALCINE.

—A Positive Solvent for Diphtheritic Membrane.—

It is with great pleasure that we present to the medical profession this new and valuable combination. In over one hundred cases in the practice, and under the personal supervision of one of the most eminent and successful practitioners, in which he tested it, the membrane was dissolved in every instance, save one. This failure was not due to the want of efficacy of the preparation, but to the inability of the little patient's parents to enforce the use of it. Its action is rapid, in the majority of cases cleaning the tonsils and fauces within twenty-four hours, and in only one case of the hundred did it take forty-eight hours to accomplish its entire removal. In a case of relapse with most frightful extension of the membrane all over the whole vault of the mouth, fauces, tonsils, and larynx, accompanied with the greatest prostration, the membrane was entirely removed in forty-eight hours.

Its medical properties are antiseptic, resolvent, astringent, disinfectant and powerfully solvent.

It is entirely non poisonous and will not injure the most delicate tissues of the youngest child. It contains: Pure Oxide of Calcium; Flores Sulphuris Loti, thoroughly washed and purified; Benzo Boracic Acid, chemically pure; Oleum Eucalyptus Globulus; Oleum Gaultheria; Extractum Pancreaticus, entirely free from fat.

At a glance we see that **Sulpho-Calcine** contains, in intimate and chemical combination, all the ingredients which have proven to be of material benefit through past experience, in dissolving the membrane of Diphtheria.

Sulpho-Calcine is used either in the form of a gargle or spray. If as a gargle, it may be used pure or, which is just as well, diluted one-half with water. But if used as a spray, it must be in the concentrated form. This also applies when used with either the swab or the camel's hair brush. If any of the medicine is swallowed, no harm will ensue, but on the contrary it will help to relieve the constitutional symptoms, by its antiseptic action, as will be readily understood by a study of its component parts.

Samples of any of our preparations sent to physicians gratuitously for trial.

REED & CARNRICK, NEW YORK.

Champagne ANALYZED

Of Interest to all Medical Practitioners.

WHAT IS SAID BY

THOMAS KING CHAMBERS, M.D., F.R.C.P.
R. OGDEN DOREMUS, M.D.
F. W. PAVY, M.D., F.R.S.

"Champagne, with a minimum of alcohol, is by far the wholesomest, and possesses remarkable exhilarating power."—THOMAS KING CHAMBERS, M.D., F.R.C.P.

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most prominent brands of Champagne. I find G. H. Mumm & Co.'s Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it not only for its purity but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M.D., *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

"Champagne, while only possessing the alcoholic strength of natural wines, is useful for exciting the flagging powers in case of exhaustion."—F. W. PAVY, M.D., F.R.S., *Lecturer on Physiology at Guy's Hospital, London.*

The remarkable vintage of 1884 of **G. H. MUMM & CO.'S EXTRA DRY CHAMPAGNE,** the finest for a number of years, is now imported into this market, and pronounced by connoisseurs unsurpassed for excellence and bouquet.

Buffalo Lithia Water in the Treatment of Stone in the Bladder—Its Solvent Properties—Its Value in Bright's Disease, Cystitis, etc.

By JOHN HERBERT CLAIBORNE, M. A., M. D., of Petersburg, Va.

Ex-President and Honorary Fellow Medical Society of Virginia, Etc.

Reprint from Virginia Medical Monthly, December, 1889.

I have for many years been prescribing the use of the Buffalo Lithia Water in cases of lithiasis, uræmia Bright's disease, cystitis, and of congener affections, and with the same marked results which have followed its exhibition in like conditions by a number of other physicians. The most striking instance, however, in which I have seen the solvent properties of the waters manifested has been in the case of Mr. Thos. D. Moss, of this city. Mr. Moss had been subject to attacks of lithiasis for several years, but in August last, after one of the most violent attacks of nephritic colic, passed gravel from the kidney into the bladder, where it remained for a week or more, setting up a severe inflammation of that viscus, with all of its painful and distressing symptoms. Finally, however, the gravel recommenced its journey, and became lodged in the prostatic portion of the urethra, cutting off the flow of urine and causing retention. Being compelled to use a catheter for the relief of this symptom, I pushed the calculus back into the bladder, as there was too much inflammation to resort to either the crushing of the stone or to its removal by lithotomy.

I put the patient to bed, restricted him to milk diet, administered opium suppositories in sufficient doses to relieve vesical tenesmus and pain, and directed him to drink the Buffalo Lithia Water in the largest quantities which he could bear. He succeeded in drinking from a half gallon to a gallon every twenty-four hours, and, at the end of about ten days, commenced to pass the detrita of the gravel, as I supposed, in quantities which seemed incredible. At all events, after passing his water upon a clean board, and allowing as much of it to flow off as would, you could then scrape up with a knife a teaspoonful or two (after every passage of urine) of phosphates, urates, etc., closely resembling whitewash which had been applied to the board, and which had there dried.

This continued for a week. I then washed out the bladder several times with a warm solution of boracic acid, and Mr. Moss was soon on his feet again. At this writing, he says that he is perfectly well, and feels, for the first time in many years, entirely free from all kidney or bladder trouble.

MEDICAL AND SURGICAL REPORTER,

P. O. BOX 843. PHILADELPHIA.

Sulfonal-Bayer has been before the Medical Profession for some time, receiving its unqualified endorsement, but the use has been limited in many cases, owing to the hesitation of the practitioner in recommending so costly a remedy.

It is a matter of gratification to us to be able to announce a substantial reduction in price of

THE NEW HYPNOTIC

SULFONAL-BAYER,

which will enable physicians to freely prescribe it whenever indicated, and will bring it within the reach of all classes of patients.

So much has been written and published regarding Sulfonal that it does not here seem necessary to set forth at length its peculiar merits. We have already published two pamphlets on this subject, and the points will be found to be fully exhibited in the series of contributions contained in them. These pamphlets will be mailed to applicants.

Sulfonal was discovered by Prof. Eugen A. Baumann, of Freiburg University, and was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

Sulfonal-Bayer is supplied by us in half-ounce and one-ounce vials.

We prepare 5-grain and 15-grain Tablets of Sulfonal-Bayer. The tablet form is admirably adapted to the purpose of administering this drug, as when they are placed in the liquids they disintegrate, and are thus received into the system.

We also put up Sulfonal-Bayer in the form of our Soluble Pills, containing 5 grains each.

ANALGESIC—ANTIPYRETIC

PHENACETINE-BAYER.

Phenacetine-Bayer (Para-Acetphenetidine) is a white, glossy, crystalline powder, perfectly tasteless, slightly soluble in water, a little more soluble in glycerine, but most freely in alcohol, and it was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

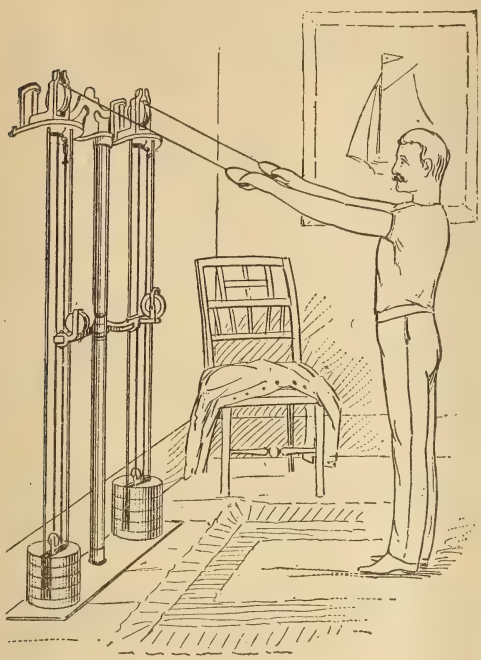
Phenacetine-Bayer has been received with great favor by the Medical Profession, and is daily growing in esteem both as an Antipyretic and Analgesic.

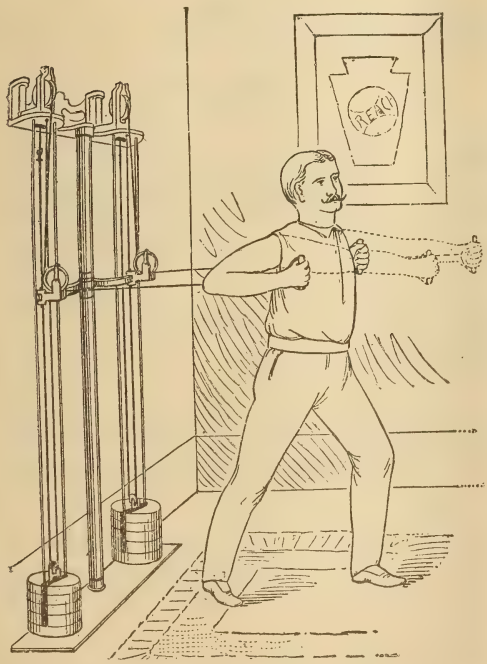
Phenacetine-Bayer is an important antineuralgic; its effect is more energetic than that of Antipyrine, and does not cause lassitude or any other disagreeable symptoms.

Our two pamphlets on Phenacetine-Bayer, containing the valuable testimony of eminent physicians, will be mailed on application.

W. H. Schieffelin & Co.,

170 & 172 William St., New York.





A. G. SPALDING & BROS.'

Gymnasium Department.

It has become a matter of record, that hereafter the **Gymnasium** in all its details will be one of the leading features of our business.

With the addition to our own valuable patents, those of the **A. J. Reach Company,** of Philadelphia, recently purchased by us, enables us to claim the most **extensive department** of **Gymnasium Appliances in the world.**

We have been encouraged in this **important** movement by the constantly increasing demand from **Colleges, Seminaries,** and other **Educational** Institutions for Gymnasium Supplies, and henceforth we shall devote special attention to furnishing **plans, specifications,** and **estimates** to such and for **private residences** as well, and solicit correspondence with all contemplating the introduction of gymnastics for any purpose.

The Peerless Pulley Weight, illustration of which appears on this page, is a most perfect appliance for the development of the **chest** and **arms,** adjustable to the height of *any* person, and in weight from five to thirty pounds. For **man or woman** this is the peer of any method yet devised, especially for home use. Realizing the attention the **medical profession** and the **teacher,** are now giving to **healthful** exercise in **schools,** we solicit also their correspondence, and any orders, or business prceeding from such, will be gratefully received, and entitled to our best rates of discount, and will receive prompt and careful attention.

Visitors to our different establishments at **Chicago, New York,** and **Philadelphia** will always be welcome and politely served by the many efficient salesmen constantly in attendance.

A Phosphorized Cerebro-Spinant

(FRELIGH'S TONIC).

FORMULA.

Ten minims of the Tonic contain the equivalents (according to the formulæ of the U. S. P., and Dispensatory) of

Tinct. Nux Strychnos,	1	minim.
" Ignatia Amara,	1	"
" Cinchona,	4	"
" Matricaria,	1	"
" Gentian,	½	"
" Columbo,	½	"
" Phosphorus, C. P.,	1-300	gr.
Aromatics,	2	minims.

Dose: 5 to 10 drops in 2 tablespoonfuls of water.

INDICATIONS.

Paralysis, Neurasthenia, Sick and Nervous Headache, Dyspepsia, Epilepsy, Locomotor Ataxia, Insomnia, Debility of Old Age, and in the Treatment of Mental and Nervous Diseases.

A BALTIMORE PHYSICIAN, WHOSE DIPLOMA DATES FROM 1825, SAYS:

"Your combination I find vastly more effective than any tonic I have ever used. It furnishes a most powerful evidence of the vastly increased power of medicament by combination and judicious pharmaceutic preparation."

Price, One Dollar per Bottle, containing 100 of the Average 5-Drop Doses.—Physicians' single sample delivered, charges prepaid, on application. That every physician may be his own judge of its value, irrespective of the opinions of others, we make the following

SPECIAL OFFER:

We will send to any physician, delivered, charges prepaid, on receipt of twenty-five cents, and his card or letter-head, half a dozen physicians' samples, sufficient to test it on as many cases for a week to ten days each. The Tonic is kept in stock regularly by all the leading wholesale druggists of the country. As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-lists, etc., address,

Permanent Pepsin.

THE INSEPARABLE STANDARDS OF VALUE ARE PERMANENCY AND ACTIVITY.

WHEN a physician prescribes pepsin and his patient finds that it "sticks to the paper," that it forms a gummy mass "in powders," he may rely upon it that FAIRCHILD'S PEPSIN has not been dispensed; if he has ordered Fairchild's, this behavior is positive evidence that he and his patient have been the victims of "substitution."

Pepsins which are hygroscopic, which do undergo upon exposure to air the changes characteristic of peptone, are offered (in the form of scales and in powder) with pretensions to permanent quality.

If a product is sought, of well-proven permanency and of highest standard of activity, FAIRCHILD'S PEPSIN is the one which will never give cause for complaint.

Fairchild's was the original "Scale Pepsin;" the first positively "free from starch, sugar, acid, peptones or any added substance." The host of imitations of "Scale Pepsin" bear witness to the value and reputation of the original.

RABUTEAU'S DRAGEES OF IRON

Laureate of the Institute of France.—Prize in Therapeutics.

The studies made by the Physicians of the Hospitals have demonstrated that the **Genuine Dragees of Iron of Rabuteau** are superior to all other preparations of Iron in cases of *Chlorosis, Anæmia, Leucorrhœa, Debility, Exhaustion, Convalescence, Weakness of Children*, and the maladies caused by the Impoverishment and Alteration of the blood after periods of fatigue, watching, and excesses of any kind.

TAKE 4 TO 6 DRAGEES DAILY.

Rabuteau's Elixir of Iron is recommended to those persons who may be unable to swallow the Dragees. Dose —*A small wineglassful with meals.*

Rabuteau's Syrup of Iron is specially designed for children. Chalybeate medication, by means of **Rabuteau's Iron,** is the most economical and the most rational known to therapeutics.

No constipation, no diarrhœa, complete assimilation.

Take only the GENUINE IRON OF RABUTEAU of

CLIN & CO., Paris.

SOLUTION OF

THE SALICYLATE OF SODA OF DOCTOR CLIN.

Laureate of the Paris Faculty of Medicine (MONTYON PRIZE).

Dr. Clin's Solution, always identical in its composition, and of an agreeable taste, permits the easy administration of *pure Salicylate of Soda*, and the variation of the dose in accordance with the indications presented.

"The *Salicylate of Soda* used by **Clin** is of perfect purity, "and is prepared with the greatest care; it is a medicament "in which we may have every confidence."

—*Paris Society of Medicine, Meeting of Feb. 8th, 1879.*

Clin's Solution, very exactly mixed, contains: 2 grammes of *Salicylate of Soda* per tablespoonful, 50 centigrammes of *Salicylate of Soda* per teaspoonful.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the **three** Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic,* is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence,* having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

ONEITA

The perfection of table waters, with mineral properties unsurpassed in the treatment of Dyspepsia, Kidney and Liver troubles, Gout, Rheumatism, etc. The analysis of the spring shows a combination of mineral virtues unequaled in any other water. The water has been before the public but a short time, yet in that time has won public favor to a marked degree. Send for analysis of C. F. Chandler, Ph. D.

ONEITA SPRING CO.,
UTICA, N. Y.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

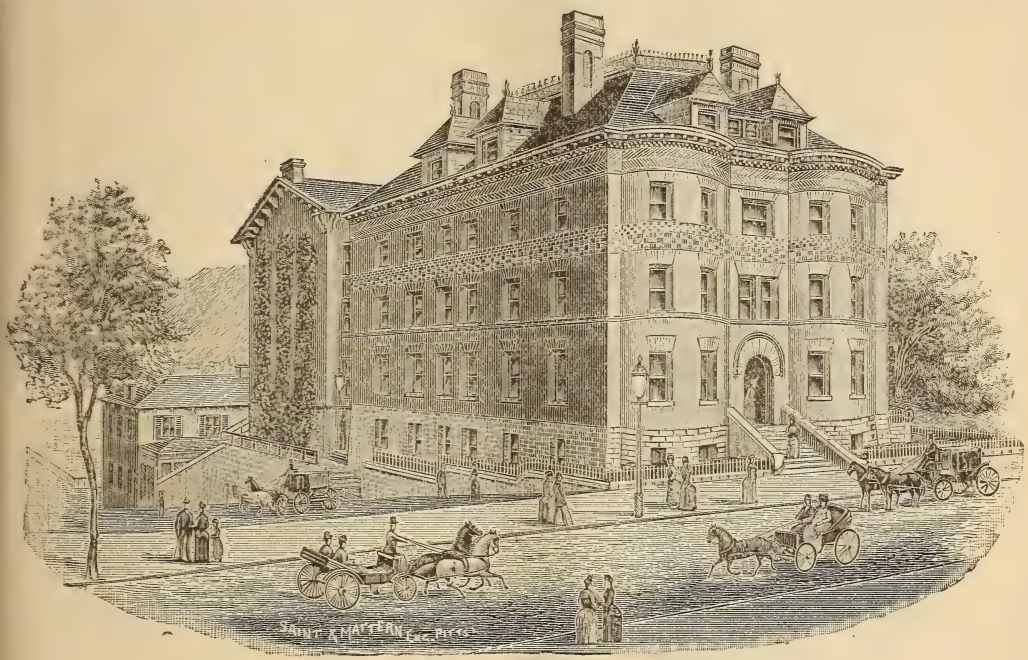
DR. R. S. SUTTON'S

Sanatorium for Diseases of Women.



Seventh Year Opens September 1, 1889.

ALLEGHENY CITY, PA.

This Institution is located on high ground, and overlooks the Allegheny, Monongahela and Ohio rivers; it commands a view of the city of Pittsburgh, and its picturesque surroundings. The building is large and beautiful, it is provided with every modern convenience, the halls are heated by steam, the rooms are commodious, well lighted and ventilated, and heated by open grates. The house is provided with a private parlor and reading-room for patients. The dining-room is large, handsomely finished, and furnished with small tables, securing privacy at meals for those who do not care to have meals served in their own rooms. Patients can be as secluded, should they desire it, as in a well appointed hotel. Each patient is examined by Dr. Sutton, and receives his daily personal attention, while Dr. J. H. Williamson, a physician of ample hospital experience, resides in the Institution, and has, under Dr. Sutton, the immediate care of the patients. The Institution accommodates 25 patients, and is equal in comfort to the best hotels.

Electricity, baths, douches, massage, local treatment, general medication and surgical operations are resorted to according to the requirements of each patient.

For further information address the Matron

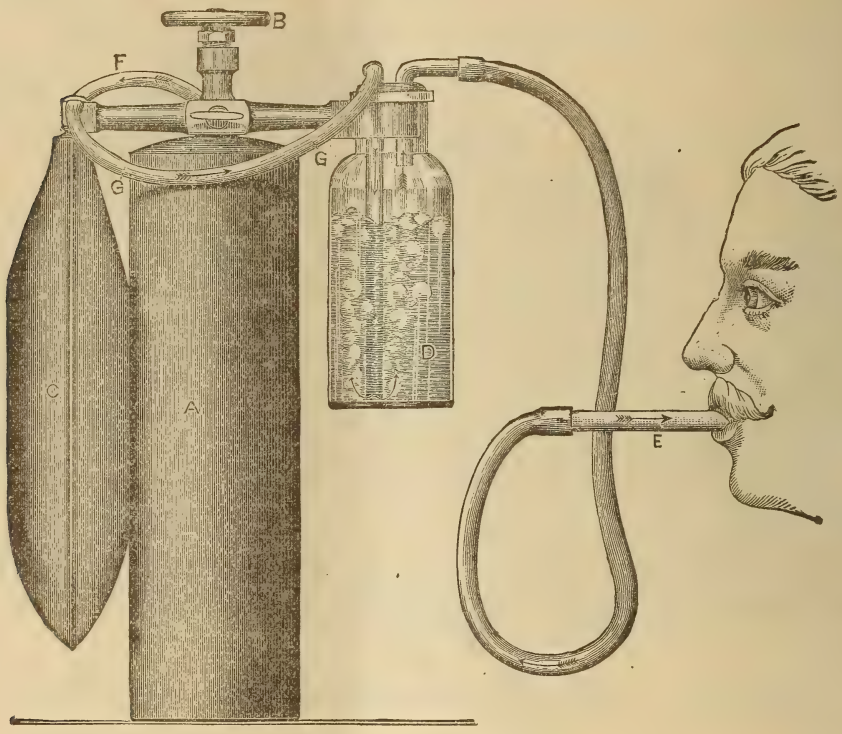
INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY OF DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request:

LAMBERT PHARMACAL CO., ST. LOUIS, MO.

CALIFORNIA VINTAGE CO.

21 PARK PLACE N.Y.

Geo Hamlin Prest. Chas Roome Parmele Treas.

GENTLEMEN:

The Case of your wines sent me for analysis by Dr. A. L. Hummel, of the "Annals of Hygiene," containing specimens of your La Rosa Zinfandel, Mataro, Riesling, Royal Tokay, and Royal Grape Brandy, has been duly received.

I have examined them for the common contaminants of wine; to wit: Sulphurous acid and sulphites, salicylic acid, fuchsin, lead salts, etc., none of which I found present therein.

I have also determined their alcoholic strength, extractives, and ashes, and found them to correspond strictly in this respect with the standard of pure and natural wines, which cannot be said of many of the imported wines.

As a native of a wine-producing country, I consider myself somewhat of a judge of wines, and regard your products as comparing more than favorably with most of the wines from abroad which are sold at higher prices, so much so that I enclose within my order for fifty bottles of La Rosa Zinfandel, which I expect to use hereafter exclusively at my table.

Very Respectfully,

L. WOLFF, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

PARIS MEDAL

TO

WILLIAM R. WARNER & CO.

W. R. WARNER & CO. have received a Silver Medal at the Paris World's Fair, being the highest of its kind, in recognition of the following claims:

First.—W. R. Warner & Co.'s Pills, quick solubility and accuracy.

Second.—Reliability and permanency unsurpassed. Also for Warner & Co.'s Effervescent Salts.

First.—Superior effervescing properties.

Second.—General elegance, excellence, and stability.

PHYSICIANS SHOULD BE CAREFUL TO SPECIFY WARNER & CO.

☞The coating of the following pill will dissolve in 4½ minutes.☜

PIL: CHALYBEATE COMP.

(WARNER & CO.)

Nux Vomica is added as an ingredient to Pill Chalybeate to increase the tonic effect when desired.

Composition of each Pill.—℞ (Chalybeate Mass.), Carb. Protoxide of Iron, gr. 2½, Ext. Nux. Vom. gr. 1-6.

DOSE—1 to 3 Pills.

Most advantageously employed in the treatment of Anæmia, Chlorosis, Phthisis, Scrofula, Loss of Appetite, etc.

PIL: ANTISEPTIC.

Each Pill contains: Sulphite Soda, 1 gr. Salicylic Acid, 1 gr. Ext. Nuc. Vomica, ¼ gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic is prescribed with great advantage in cases of Dyspepsia attended with acid stomach and enfeebled digestion following excessive indulgence in eating or drinking. It is used with advantage in Rheumatism.

Prepared by WM. R. WARNER & CO.

PIL: ANTISEPTIC COMP.

(WARNER & CO.)

Each pill contains: Sulphite Soda, 1 gr. Salicylic Acid, 1 gr. Ext. Nuc. Vomica, ⅛ gr. Powd. Capsicum, 1-10 gr. Conc't Pepsin, 1 gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic Comp. are prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food.

Supplied upon physician's prescription by all leading druggists. Take no substitute.

1228 MARKET ST., Phila. 18 LIBERTY ST., New York.

The Acutely Ill.

When a patient is acutely ill, the digestive powers share in the general condition, and consequently the food supplied should be of the most easily assimilable character. The predigestion of starchy matters outside the body, as in MELLIN'S FOOD, is necessary, and the soluble carbohydrates of which this food consists, soluble because predigested, form the true food of the acutely ill.—J. MILNER FOTHERGILL, M.D., Edin.

A sample of MELLIN'S FOOD *will be sent to any physician, free of expense, upon application.*

Doliber-Goodale Co., Boston, Mass.

Apollinaris

"THE QUEEN OF TABLE WATERS."

The filling at the Apollinaris Spring (Rhenish Prussia), amounted to

11,894,000 BOTTLES IN **1887,**
12,720,000 BOTTLES IN **1888,** AND
15,822,000 BOTTLES IN **1889.**

"The annual consumption of this favorite beverage affords a striking proof of the widespread demand which exists for table water of absolute purity, and it is satisfactory to find that, wherever one travels, in either hemisphere, it is to be met with; it is ubiquitous, and should be known as the cosmopolitan table water. 'Quod ab omnibus, quod ubique.'"—BRITISH MEDICAL JOURNAL.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

THE VALUE OF NUTRITION IN DISEASE.

All physicians who have ever used Murdock's Liquid Food and Suppositories recognize their value over all other foods, in breaking up disease and building up the patients after disease, preventing a relapse, **as the same results are obtained as in surgery.** Its value in surgical cases we illustrate by the records of the different cities and of Murdock's Free Surgical Hospital for Women, which is the largest in the United States. It contains 114 beds, every bed free, including operation, the operations ranging from 1000 to 1200 yearly, representing 90 of the worst classes known in surgery. Among these cases we have had **Cancer of uterus** (*Kolpo-hysterectomy*), 13; **Salpingitis** (*Tait's operation*), 31; **Fibroid of uterus** (*abdominal hysterectomy*), 19; **Ventral operation, hernia,** (*abdominal section*), 12; **Cancer of bowel** (*incision*), 2; **Parovarian cyst, 6; Papillomatous cyst** (*extirpation*), 4; **Tubercular peritonitis** (*incision*), 1, **Ovarian cystoma 27; Nymphomania** (*Battey*), 1; **Exploratory abdominal incisions, 12; Fibroid with abdominal abscess** (*Hegar*), 2; **Hysterorraphy, 2; Dermoid cyst, 3; Cirrhotic ovaries,** (*Battey*), 4; **Fibroid uterus** (*Hegar*), 6; **Hystero-epilepsy** (*Battey*), 1; **Haemato-Salpinx** (*Tait*), 5; **Rupture of intestine into vagina, 1; Dislocated kidney, 2; Fibroid tumor abdominal wall, 1; Resection of intestine** (*Senn*), 1; **Ruptured perineum, 294.** Patients are in the Hospital 8 days before and 26 days after operation, on an average.

In Boston, last year, 42 deaths were from Cancer in the Breast. In Murdock's Hospital, 35 such cases were operated on without a death, the patients remaining in the Hospital, on an average, 18 days.

Mortality	in Boston,	25.60	per 1000.
"	of Women in Boston,	29,00	" "
"	**in Murdock's Free Surgical Hospital,**	**5.00**	" "
"	New York,	26.32	" "
"	Philadelphia,	20.00	" "
"	Chicago,	20.90	" "
"	St. Louis,	20.49	" "

showing our mortality is only one-sixth as great as of those in health. As good results were obtained in our General Hospital, which we kept open 27 months, **thus showing the value of nutrition as found in Murdock's Liquid Food, and so recognized by the British and American Medical Associations,** before which essays were read and discussed, and it is the only Raw food preparation on which essays were ever read.

Physicians are invited to visit our Hospitals and Works, also to send in patients and to be present at the operations. For any physician who has not used our Liquid Food (and Suppositories for adults and infants), we will deliver free samples to any express company in Boston.

When babies do not thrive, never change their food, but add five or more drops at each feeding of Murdock's Liquid Food, and their lost or needed vitality will be restored in less than thirty days. It is invaluable when weaning babies or when teething. If mothers will take one teaspoonful to a tablespoonful before each meal and on retiring, they will receive as much benefit as the baby.

Murdock Liquid Food Co., Boston.

GOUDRON DE BLOUNT

PREPARED FROM THE GENUINE CAROLINA TAR.

DOSE.—One fluid drachm four or more times a day (as indicated), either full strength, diluted, or, in combination.

INDICATIONS.—Chronic and acute affections of the Air Passages, Coughs, Colds, Bronchitis, Asthma and Consumption.

WILLIAM MURRELL, M.D., F.R.C.P.,

Lecturer on Pharmacology and Therapeutics at the Westminster Hospital; Examiner in Materic Medica to the Royal College of Physicians of London; Fellow of the Medico-Chirurgical College of Philadelphia,

Says:—"I have used with success 'Goudron de Blount.' The results have been good, and the preparation is popular with patients."

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

ALETRIS CORDIAL

UTERINE TONIC AND RESTORATIVE.

Prepared from the Aletris Farinosa or True Unicorn and Aromatics.

INDICATIONS.

Amenorrhea, Dysmenorrhea, Leucorrhea, Prolapsus Uteri, Sterility, to Prevent Miscarriage, Etc.

DOSE:—ONE TEASPOONFUL THREE OR FOUR TIMES A DAY.

UNRIVALED AS A UTERINE TONIC IN IRREGULAR, PAINFUL, SUPPRESSED AND EXCESSIVE MENSTRUATION.

It Restores Normal Action to the Uterus, and Imparts Vigor to the Entire Uterine System.

☞Where women have miscarried during previous pregnancies, or in any case where miscarriage is feared, the ALETRIS CORDIAL is indicated, and should be continuously administered during entire gestation.

CHAS. CLAY, M. R. C. S., Manor House, Dewsbury, England, says:—I find Aletris Cordial (Rio) is of great service in threatened miscarriage.

FRANCIS E. CANE, L. R. C. S., &c., Leeds, England, says:—I have tried the Aletris Cordial (Rio) in two cases of long standing dysmenorrhea, with excellent results. One of these patients has spent a week in bed every month for two years. After all the usual remedies, I put her on Aletris Cordial, and for the last two periods she has been out and about all the time.

L. M. WATSON, M. D., Delhi, Ills., says:—I have used Aletris Cordial (Rio) in cases of dysmenorrhea, suppressed menses and threatened miscarriage, and also, combined with Celerina, as a tonic after confinement, with the happiest results, and now I am using it on a case of leucorrhea, with injections of S. H. Kennedy's Extract of Pinus Canadensis, and it is acting like a charm.

P. H. OWEN, M. D., Morganville, Ala., says:—I have prescribed Aletris Cordial (Rio) in several cases with the most satisfactory results, and regard it as the best uterine tonic I have met with in a professional experience of over twenty-five years. In cases of threatened miscarriage it acts like a charm. Would recommend its continuous administration in all cases when there is any indication of miscarriage.

Dr. W. BERTHELOT, Santander, Spain, says:—I have tried the Aletris Cordial (Rio), and it has seemed to me to be useful, especially in cases of dysmenorrhea.

Dr. RASQUINET, Jupile, near Liege, Belgium, says:—I tried Aletris Cordial (Rio) in the case of a woman who had had several miscarriages at the end of five months, and who is now again pregnant, having reached the seventh month, thanks to Aletris Cordial.

R. REECE, M. R. C. S., Walton-on-Thames, England, says:—Aletris Cordial (Rio) in painful menstruation is most valuable. A wife of a minister suffered much, and had had three miscarriages I prescribed Aletris Cordial. She has for the first time, gone her full time, and was safely confined with a male child.

J. T. COLLIER, M. D., Brooks, Me., says:—I have used your Aletris Cordial (Rio) in cases of females at the menopause. Consider it one of the finest remedies for these cases.

Dr. GORDILLON, St. Amand, France, says: I have tried the Aletris Cordial (Rio) in a case of dysmenorrhea. The result I obtained from the use of your preparation was excellent, better than I had obtained in the same patient by prescribing the usual remedies employed in such cases.

W. F. TOOMBS, M. D., Morrillton, Ark., says:—I have used a great deal of your Aletris Cordial (Rio) and I find it all you claim for it in amenorrhea, dysmenorrhea, metritis, leucorrhea; I don't think it has an equal. I have used it in two cases of threatened miscarriage and the trouble was obviated. For a general Uterine Tonic I know of nothing superior.

R. D. PATTERSON, L. R. C. S. &c., Medical Officer, Caledon Dispensary, Co. Tyrone, Ireland, says:—I have very great pleasure in testifying to the very high opinion I hold of Aletris Cordial (Rio) in threatened miscarriage.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

E. FOUGERA & CO., 30 North William St., New York,

Sole Agents for the above Preparations.

Doctor, we offer You a complete solution of the Question of Infant Feeding.

It is universally conceded that Mother's Milk of good quality is the best nutriment for infants.

This is the nourishment that we enable nursing mothers to supply abundantly.

When our new preparation, **NUTROLACTIS**, is given to nursing mothers whose milk is scanty, although the breasts are almost entirely dry, it will in the course of two days, or three at farthest, so increase the quantity that there will be milk enough to completely nourish a vigorous infant; the quality of the milk will be good, and at the same time the health and strength of the mother will be improved.

If the quantity of a mother's milk be adequate but the quality poor, lacking in nutritive elements, the use of this remedy will quickly and notably improve the quality and maintain the quantity until the end of normal lactation.

Physicians are assured that its use is always perfectly harmless.

Formula, Galega officinalis, G. Apolinea, G. Tephrosia. See Stillé & Maisch's National Dispensatory.

UNIVERSITY OF PENNSYLVANIA.—Medical Department.

The 124TH ANNUAL WINTER SESSION began Tuesday, October 1st, 1889, at 12 M., and will continue until May 1st, 1890.
The PRELIMINARY SESSION began September 18th, 1889.

The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology, with Bedside Instruction in Medicine, Surgery and Gynecology are a part of the regular course and without additional expense.

FACULTY.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
D. HAYES AGNEW, M.D, LL.D., Honorary Professor of Clinical Surgery.
WILLIAM PEPPER, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
WILLIAM GOODELL, M.D., Professor of Gynecology.
JAMES TYSON, M.D., Professor of Clinical Medicine.
HORATIO C. WOOD, M.D., LL.D, Professor of Materia Medica, Pharmacy and General Therapeutics.
THEODORE G. WORMLEY, M.D., LL.D., Professor of Chemistry and Toxicology.
JOHN ASHHURST, JR., M.D., Professor of Surgery and of Clinical Surgery.
EDWARD T. REICHERT, M.D., Professor of Physiology.
WILLIAM F. NORRIS, M.D., Honorary Prof. of Ophthalmology
BARTON COOKE HIRST, M.D., Professor of Obstetrics.
J. WILLIAM WHITE, M.D., Professor of Clinical Surgery.
JOHN GUITÉRAS M.D., Professor of General Pathology and Morbid Anatomy.
GEORGE A. PIERSOL, M.D., Professor of Histology and Embryology.
SAMUEL G. DIXON, M.D., Professor of Hygiene.

For Catalogue and announcement containing particulars, apply to

DR. JAMES TYSON, Dean,
36th and Woodland Avenue, Philadelphia.

WESTERN PENNSYLVANIA MEDICAL COLLEGE

CITY OF PITTSBURGH.

SESSIONS OF 1889—90.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. J. W. J. McKENNAN.

Business correspondence should be addressed to
PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

NATIONAL MEDICAL COLLEGE.

MEDICAL DEPARTMENT OF THE

COLUMBIAN UNIVERSITY,

WASHINGTON, D. C.

The 68th Annual Session will begin October 7th and end March 1st. Graded three years' course required. Women admitted. Professors: J. F. Thompson, W. W. Johnston, A. F. A. King, E. T. Fristoe, Wm. Lee, D. W. Prentiss, D. K. Shute.

For circulars, address

A. F. A. KING, M. D., DEAN, 726 THIRTEENTH ST., N. W., WASHINGTON D. C.

DETROIT COLLEGE OF MEDICINE.

SESSION 1889-90.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, Sept. 25, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins April 2d, 1890; and closes June 11th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

FACULTY:

JAMES R. LEAMING, M.D., Emeritus Professor of Diseases of the Chest and Physical Diagnosis; Special Consulting Physician in Chest Diseases to St. Luke's Hospital.

EDWARD B. BRONSON, M.D., Professor of Dermatology; Visiting Dermatologist to the Charity Hospital; Consulting Dermatologist to Bellevue Hospital (Out-door Department).

A. G. GERSTER, M.D., Professor of Surgery; Visiting Surgeon to the German and Mt. Sinai Hospitals.

V. P. GIBNEY, M.D., Professor of Orthopædic Surgery; Orthopædic Surgeon to the Nursery and Child's Hospital; Surgeon in-Chief to the Hospital for Ruptured and Crippled.

LANDON CARTER GRAY, M.D., Professor of Diseases of the Mind and Nervous System; Attending Physician to Hospital for Nervous and Mental Diseases, and to St. Mary's Hospital.

EMIL GRUENING, M.D., Professor of Ophthalmology; Visiting Ophthalmologist to Mt. Sinai Hospital, and to the German Hospital.

*JAMES B. HUNTER, M.D, Professor of Gynæcology; Surgeon to the Woman's Hospital; Surgeon to the New York Cancer Hospital; Consulting Surgeon to the New York Infirmary for Women and Children; President of the Faculty.

PAUL F. MUNDÉ, M.D., Professor of Gynæcology; Gynæcologist to Mt. Sinai Hospital; Consulting Gynæcologist to St. Elizabeth Hospital.

A. R. ROBINSON, M.D., Professor of Dermatology; Professor of Normal and Pathological Histology in the Woman's Medical College.

DAVID WEBSTER M.D., Professor of Ophthalmology; Surgeon to the Manhattan Eye and Ear Hospital.

JOHN A. WYETH, M.D., Professor of Surgery; Visiting Surgeon to Mt. Sinai Hospital; Consulting Surgeon to St. Elizabeth Hospital; Secretary of the Faculty.

W. GILL WYLIE, M.D., Professor of Gynæcology; Gynæcologist to Bellevue Hospital.

R. C. M. PAGE, M. D., Professor of General Medicine and Diseases of the Chest; Physician to St. Elizabeth Hospital; Attending Physician to the Northwestern Dispensary, Department of Chest Diseases.

D. BRYSON DELAVAN, M. D., Professor of Laryngology and Rhinology; Laryngologist to the Demilt Dispensary.

JOSEPH WILLIAM GLEITSMANN, M. D., Professor of Laryngology and Rhinology; Laryngologist and Octologist to the German Dispensary.

OREN D. POMEROY, M D., Professor of Otology; Surgeon Manhattan Eye and Ear Hospital; Ophthalmic Surgeon to New York Infants' Asylum, and Consulting Surgeon to the Paterson Eye and Ear Infirmary.

HENRY N. HEINEMAN, M. D., Professor of General Medicine and Diseases of the Chest; Attending Physician to Mt. Sinai Hospital.

B. SACHS, M.D., Professor of Diseases of the Mind and Nervous System; Consulting Neurologist to the Montefiore Home for Chronic Invalids.

THOMAS R. POOLEY, M.D., Professor of Ophthalmology; Surgeon-in-Chief of the New Amsterdam Eye and Ear Hospital; Ophthalmic Surgeon to the Sheltering Arms; Consulting Ophthalmologist to the St. Bartholomew's Hospital.

L. EMMETT HOLT, M.D., Professor of Diseases of Children; Visiting Physician to the New York Infant Asylum; Consulting Physician to the Hospital for Ruptured and Crippled.

AUGUST SEIBERT, M.D., Professor of Diseases of Children; Physician to the Children's Department of the German Dispensary.

H. MARION SIMS, M.D., Professor of Gynæcology; Gynæcologist to St. Elizabeth Hospital and New York Infant Asylum.

WILLIAM F. FLUHRER, M.D., Professor of Genito-Urinary Surgery; Surgeon to Bellevue and St. Sinai Hospitals.

HENRY C. COE, M. D., M. R. C. S. (Eng.), Professor of Gynecology; Attending Surgeon to New York Cancer Hospital; Assistant Surgeon to Woman's Hospital; Obstetric Surgeon to Maternity Hospital; Obstetrician to New York Infant Asylum; Gynecologist to Presbyterian Hospital, Out-door Department.

* Deceased.

THE NEW YORK POLYCLINIC is a School of Clinical Medicine and Surgery for *Practitioners only*. No didactic lectures are given The classes are limited. The demonstrations are made at the Polyclinic School and Hospital, and in the various Hospitals in New York City with which the Faculty are connected.

Session of 1889-90 opens Monday, September 16th, 1889. For further information and for catalogue, address

JOHN A. WYETH, M.D.,
Secretary of the Faculty,

Or WILLIS O. DAVIS, Clerk,
214, 216 & 218 East 34th Street, New York City.

ANTIFEBRIN in INFLUENZA!

THIS USE of this Renowned Antipyretic, Anodyne, Sedative, and Nervine seems suggested by the following judgments passed on it by reputed authorities in Symptomatically **ALLIED COMPLAINTS:**

As an ANTIFEBRILE Dose: 2 to 4 grains **single**; 16 to 32 grains **daily.**—(Weinstein, Vienna.)

As an ANODYNE and NERVINE Dose in severest Neurotic and Secondary pains: 8 to 16 grains, **one to four times per day.**—(Demieville, Lausanne.)

MODE OF ADMINISTRATION:

"Even the **initial dose** of seven and a half grains gave evident relief; commonly within half an hour. If this did not suffice to break up the symptoms materially, a second dose of equal magnitude followed in an hour or two; at the very utmost a third one was given the same day.

"The remedy was effective and well tolerated at all times; at all hours of the day; on an empty or a full stomach; even during menstruation.

"The form of exhibition was that of **powders,** wrapped in **wafers.** The readier solubility of the Antifebrin in Alcohol indicates the advisability of following the dose by a small draught of Wine or Brandy."—(OTT, Prague.)

ANTIFEBRIN WAS FOUND SUPERIOR TO THE FOLLOWING REMEDIES IN EFFICACY, OR IN SAFETY, OR IN BOTH:

Antipyrine, Quinine, Morphine, Opium, Chloral Hydrate, Aconite, Caffeine, Kairine, **Salicylic Acid,** Carbolic Acid, **Bromides,** Iodides.

Among the Medical Authorities from whose Clinical and other published reports, the above-stated **Preferences of ANTIFEBRIN over other Remedies** have been drawn, are the following:

Hare, University of Pennsylvania; **Dujardin-Beaumetz,** Paris; **Herczel,** Heidelberg; **Murray,** *Brit. Med. Journal*; **Pavaivajna,** *Centralbl f. d. ges. Therapie*; **Barr,** Bridgeport, Ill.; **Kell,** Delphos, O.; **Hay,** New York; **Haas,** Prague.

Antifebrin was also found to be:

"Thoroughly **reliable** as an **ANTIPYRETIC.**"—(Demme, Berne.)
"**Not only** powerfully **ANTITHERMIC,** but also a most **useful NERVINE.**"—(Lepine, Lyons.)
"**A powerful, safe,** and **certain ANTITHERMIC** agent."—(Evans, Easton, Pa.)
"**Complete ANALGETIC** effect in nine cases out of every ten."—(Fischer, Canstatt.)

A **MAN** IS KNOWN BY THE COMPANY HE KEEPS, AND

A **DOCTOR** BY THE JOURNAL HE TAKES.

We believe the readers of the ***Medical and Surgical Reporter*** would appreciate the ***PITTSBURGH MEDICAL REVIEW,*** and on the receipt of a postal card we will mail the ***REVIEW*** to your address for 3 months free of charge. We promise to do this because we are sure you will like it and subscribe.

Pittsburgh Medical Review,

924 Penn Avenue, Pittsburgh, Pa.

EXCERPTS.

PHENACETINE.—Dr. DUJARDIN-BEAUMETZ, Paris.—"It is above all as an analgesic that Phenacetine outrivals its predecessors. While it is quite as powerful as antipyrin and acetanilid, it does not cause the pain in the stomach, or the scarlatina-form rash of the former; nor does it give rise to the cyanosis of the latter. However prolonged may be its administration—and we have given it for months in doses of 1.0 to 2.0 Gm. (15 to 30 grains) per day—we have never observed any bad effect. We have used it for the relief of every form of pain (neuralgias, migraine, rheumatic pains, muscular rheumatism, acute articular rheumatism, the lightning pains of tabes, etc.) and always with the best results."

M. F. PRICE, M. D., President Southern California Medical Society.—"A patient says, 'I have headache,' and I order Phenacetine with confidence, and always with a report of relief."

THOS. W. AYERS, M. D., Jacksonville, Ala.—"As an antipyretic I have had nothing but the very best results from its use. As an antineuralgic there is no question, but it is superior to antipyrin. It is much more energetic in its action than either antipyrin or antifebrin."

SULFONAL.—HUNTER MCGUIRE, M. D., Richmond, Va.—"Has found it particularly valuable in insomnia following the use of alcohol."

HENRY M. WETHERILL, JR., M. D., Ph. G., Philadelphia.—"The almost universal report of Sulfonal is that it has little or no effect upon the vast majority of insomnous subjects save the important one of increasing, prolonging the natural tendency to sleep; that its action is not narcotic but purely hypnotic."

W. H. FLINT, M. D., New York (Discussion before N. Y. State Medical Association).—"He had used Sulfonal as being the most efficient or desirable of the new hypnotics. He had not yet seen a Sulfonal habit. There had been about eighty per cent. of successes in his cases."

JAMES STEWART, M. D., Montreal.—"Sulfonal produces no disagreeable secondary symptoms nor any unfavorable effects on the heart or circulation. Its action was by giving rest to the cells of the cerebral cortex and thereby causing sleep."

Sulfonal-Bayer has been before the Medical Profession for some time, receiving its unqualified endorsement, but the use has been limited in many cases, owing to the hesitation of the practicioner in recommending so costly a remedy.

A substantial reduction in price having been made, it enables physicians to freely prescribe it whenever indicated, and brings it within the reach of all classes of patients.

SAVE MONEY

IN BUYING BOOKS.

By special arrangement with the publishers we are able AT THIS TIME to offer to **OUR SUBSCRIBERS** certain valuable books at a very **LOW PRICE.**

☞This can be done only in connection with paid-up subscriptions.☜

FOR $10.00 we will send the **REPORTER** for one year, **$5.00**
and **DICTIONARY OF PRACTICAL SURGERY.** By various British Hospital Surgeons. Edited by Christopher Heath, F. R. C. S. One volume, 8vo. Over 2,000 pages. Cloth, ... **$7.50**

"A most excellent book for the library of the surgeon, and especially for the country practitioner; as a book of reference it is so concise and at the same time so complete."—C. B. PORTER, M. D., Boston, Mass.

"As a means of ready reference for the student and busy practitioner this book stands unexcelled."—N. SENN, M. D.

FOR $9.00 we will send the **REPORTER** for one year, **$5.00**
and **THOMAS'S MEDICAL DICTIONARY.** A complete Pronouncing Medical Dictionary. Embracing the Terminology of Medicine and the kindred Sciences, with their signification, etymology, and pronunciation. With an Appendix, comprising an explanation of the Latin terms and phrases occurring in Medicine, Anatomy, Pharmacy, etc., together with the necessary directions for writing Latin Prescriptions, etc., etc. By Joseph Thomas, M. D., LL.D. Imperial 8vo. 844 pages. Sheep, ... **$6.00**

"It is just the book for a medical or any other student, and it should be in the office of every physician. This dictionary supplies a place that has never been filled. I have looked it through and find all the new words that I have sought."—PROF. A. F. PATTON, College of Physicians and Surgeons, Boston, Mass.

Or, **TREATISE ON HUMAN ANATOMY, by JOSEPH LEIDY, M. D.,** Professor of Anatomy in the University of Pennsylvania, etc., etc. New (second) edition, rewritten and enlarged. Containing 495 illustrations. 8vo. Extra cloth, ... **$6.00**

"The student can master and retain a practical knowledge of anatomy in a shorter time and with less hard work from this text-book than from any other work extant, and it has been our privilege to teach anatomy for several years."—MEDICAL ADVANCE, Ann Arbor, Mich.

FOR $6.50 we will send the **REPORTER** for one year, **$5.00**
VIRCHOW'S CELLULAR PATHOLOGY, as based upon Physiological and Pathological Histology. Twenty lectures delivered at the Pathological Institute of Berlin. Translated from the Second Edition by F. Chance, M. D. 134 illustrations. Eighth American Ed. Cloth, **$3.00**

Or, **DAY. DISEASES OF CHILDREN.** A practical and systematic treatise for practitioners and students. By Wm. H. Day, M. D. Second edition. Rewritten and very much enlarged. 8vo. 752 pages. Price, Cloth, ... **$3.00**

Or, **HARLEY. DISEASES OF THE LIVER,** with or without Jaundice. Diagnosis and Treatment. By George Harley, M. D. With colored plates and numerous illustrations. 8vo. Price, Cloth, ... **$3.00**

FOR $6.00 we will send the **REPORTER** for one year, **$5.00**
and any two of the following books:

1.—THE NURSING AND CARE OF THE NERVOUS AND THE INSANE. By Chas. K. Mills, M. D., ... **$1.00**

2.—MATERNITY; INFANCY; CHILDHOOD. By John M. Keating, M. D., **$1.00**

3.—OUTLINES FOR THE MANAGEMENT OF DIET; or, The Regulation of Food to the Requirements of Health and the Treatment of Disease. By E. T. Bruen, M. D., **$1.00**

4.—FEVER NURSING. Designed for the use of professional and other Nurses. By J. C. Wilson, A. M., M. D., ... **$1.00**

5.—DISEASES AND INJURIES OF THE EAR: Their Prevention and Cure. By Chas. H. Burnett, A. M., M. D., ... **$1.00**

Or, **FOR $6.00,** any one of the above Nursing Books and **THOMSON'S (Sir Henry) SURGERY OF THE URINARY ORGANS.** Some important points connected with the Surgery of the Urinary Organs. Illustrated. Cloth, ... **$1.25**

JOHN WYETH & BROTHER'S

We claim for our Hypodermic Tablets:

Absolute Accuracy of Dose.
Ready and Entire Solubility.
Perfect Preservation of the Drug.

Their convenience and utility will at once be apparent on examination.

They are put up in Cylindrical Tubes, convenient for carrying in Hypodermic or Pocket case, ten tubes in a box, with twenty tablets in each tube.

NOTE.—It will only be necessary in ordering to specify the numbers, as above. Wyeth's Manufacture. These Tablets will be sent by mail, on receipt of the proper amount.

PHILADELPHIA, PA.

Therapeutic Points.

Use McArthur's Syrup (Syrup Hypophos. Comp., C. P., McArthur) for Consumption, as it rapidly repairs the waste and restores vigor to the system.

For Tuberculosis in all forms, as it invigorates the tissue cells and enables them to overcome and expel the disease germs.

For Scrofula, as it builds up the tissue walls and thus breaks up the various inflammatory and suppurative processes incident to this diathesis.

For Inflammatory Diseases of the Throat, Bronchial Tubes, and Lungs, as its tonic and healing properties are nowhere better manifested than in this class of diseases.

For Rachitis, and all osseous degeneration, as it rapidly repairs bone tissue.

For Teething of Infants, as it furnishes food to the growing teeth. For the same reason you should give it to the nursing mothers and those whose teeth and bones are suffering during pregnancy.

For Chronic Diarrhœa, Leucorrhea, Suppurating Discharges and Sores.

For Chronic Alcoholism, the Morphine Habit, Brain Exhaustion, Loss of Memory, Neurasthenia, Spermatorrhea, Impotence, and all derangements of the nervous system. Here, by building up and restoring the nerve tissue, it effects a permanent cure, raising the patient from despondency to renewed hope and confidence, from weakness to strength and vigor.

For Uterine Fibroids and all forms of perverted nutrition, where it restores the normal processes of nutrition, and effects a recovery at once gratifying to the patient and satisfactory to the physician.

To obtain the best results, the Syrup should be given for a long time—weeks, months, and even years—until the disease is entirely eradicated and the patient no more susceptible to its return than if it "never had occurred."

As it is made only for Physicians' prescriptions, there are no labels, etc., on the bottle.

We will send our valuable treatise on "The Curability and Treatment of Consumption," free to any physician.

McARTHUR HYPOPHOSPHITE CO.,
BOSTON, MASS.

INFLUENZA. EXALGINE. INFLUENZA.

THIS analgesic has been very successfully used in France in the treatment of the Cephalalgia and muscle pains of La Grippe, by Doctors BRIGONNET, DUJARDIN-BEAUMETZ, DESNOS, BARDET, MICHAUX, and others. The dose is **2** to **4** grains, three or four times a day.

Exalgine is offered in one ounce tins, in gelatine-coated pills of **2, 3, 5** grains, and in the form of a cordial; **Cordial Exalgimine.**

ANTIFEBRIN in INFLUENZA!

THIS USE of this Renowned Antipyretic, Anodyne, Sedative, and Nervine seems suggested by the following judgments passed on it by reputed authorities in Symptomatically **ALLIED COMPLAINTS:**

As an ANTIFEBRILE Dose: 2 to 4 grains **single**; 16 to 32 grains **daily.**—(Weinstein, Vienna.)

As an ANODYNE and NERVINE Dose in severest Neurotic and Secondary pains: 8 to 16 grains, **one to four times per day.**—(Demieville, Lausanne.)

MODE OF ADMINISTRATION:

"Even the **initial dose** of seven and a half grains gave evident relief; commonly within half an hour. If this did not suffice to break up the symptoms materially, a second dose of equal magnitude followed in an hour or two; at the very utmost a third one was given the same day.

"The remedy was effective and well tolerated at all times; at all hours of the day; on an empty or a full stomach; even during menstruation.

"The form of exhibition was that of **powders**, wrapped in **wafers.** The readier solubility of the Antifebrin in Alcohol indicates the advisability of following the dose by a small draught of Wine or Brandy."—(Orr, Prague.)

ANTIFEBRIN WAS FOUND SUPERIOR TO THE FOLLOWING REMEDIES IN EFFICACY, OR IN SAFETY, OR IN BOTH:

Antipyrine, Quinine, Morphine, Opium, Chloral Hydrate, Aconite, Caffeine, Kairine, Salicylic Acid, Carbolic Acid, Bromides, Iodides.

Among the Medical Authorities from whose Clinical and other published reports, the above-stated **Preferences of ANTIFEBRIN over other Remedies** have been drawn are the following:

Hare, University of Pennsylvania; **Dujardin-Beaumetz**, Paris; **Herczel**, Heidelberg; **Murray**, *Brit. Med. Journal*; **Pavaivajna**, *Centralbl f. d. ges. Therapie*; **Barr**, Bridgeport, Ill.; **Kell**, Delphos, O.; **Hay**, New York; **Haas**, Prague.

Antifebrin was also found to be:

"Thoroughly **reliable** as an **ANTIPYRETIC.**"—(Demme Berne)
"**Not only** powerfully **ANTITHERMIC**, but also a most **useful NERVINE.**"—(Lepine, Lyons.)
"**A powerful, safe,** and **certain ANTITHERMIC** agent."—(Evans, Easton, Pa.)
"**Complete ANALGETIC** effect in nine cases out of every ten."—(Fischer, Canstatt.)

PIL. PHENACETINE ET SALOL, 5 GRS., "W. H. S. & CO."

{Phenacetine-Bayer, ... 2½ grs.}
{Salol, ... 2½ grs.}

Anti-Rheumatic and Analgesic. This combination was first suggested by Dr. M. F. Price, Colton, Cal., President of the "Southern California Medical Society." In an address to the members he says: "In a case of acute Rheumatism, affecting elbows, wrists, knees, and ankles, ordered Phenacetine and Salol every three hours. No local application ordered. Made five daily visits, found the patient each day improved, discharged with orders to continue the medicine three times a day for a week."

After citing other cases, one of Sciatica where the patient was suffering such pain that the slightest motion caused faintness with nausea and continuous vomiting; two with acute Rheumatism, and one with Neuralgia of the stomach, Dr. Price continues:

"It will be observed that in some of these cases I have combined Salol with Phenacetine. I did this on the principle of the well-known effect of Salicylic Acid in rheumatism, but I rely on the Phenacetine for the relief of the pain, and in this way perhaps the cure of the disease causing it." *Southern California Practitioner, August,* 1889.)

PIL. TERPIN HYDRAT., 2 GRS., "W. H. S. & CO."

A new and potent remedy in the treatment of coughs, catarrh, bronchitis, and kindred diseases.

Terpin Hydrate is indicated in cases where violent irritation of the bronchial mucous membrane exists, and where the secretion is inconsiderable and peculiarly viscid, such as is met with in the chronic catarrh accompanying emphysema and phthisis. The effect obtained is always an increase and a liquefaction of the secretion, a considerable reduction of the irritation, and easy expectoration.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced in their present excellent quality.

The conditions of a perfect Pill are:

1*st.* *Ingredients of the finest quality.*
2*d.* *All materials weighed with scrupulous exactness.*
3*d.* *The mass sufficiently consistent to maintain the globular form, and yet readily soluble in the stomach.*
4*th.* *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

The continued favor which has been shown to our **Soluble Pills** is sufficient evidence that care has been bestowed upon their manufacture.

As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test, either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque, nor insoluble, but elastic, thin, transparent, and readily soluble.

For further information about them we refer to our formula books and price lists, which we shall be happy to furnish upon application.

A Peerless Chemico-Physiological Food and Restorative

Crystalline Phosphate

A TISSUE FOOD

PHOSPHATIC FOOD PRODUCTS TRADE MARK

Contains all essential inorganic components of the tissues in a semi-solid, easily soluble, crystalline mass,

COMPOSED OF

ACID PHOSPHATE OF CALCIUM.

WITH

Acid Phosphate of Magnesium,
" " " Iron,
" " " Sodium,
" " " Potassium,
Chloride of Potassium,
" " Sodium
Sulphate of Potassium,
and Phosphoric acid.

INDICATIONS:

STOMACH DISORDERS, such as Indigestion, Flatulence Gastric Catarrh, and Poor Appetite, Constipation, etc.

WRONGS OF NUTRITION, as in Scrofula, Rickets, Caries, Marasmus, Delayed Union of Fractures, Necrosis of Tissue, Difficult or Delayed Dentition and Development, etc.

NERVOUS AND GENERAL DEBILITY AND SLEEPLESSNESS, as from Sexual Excess, Venerial Disease, Childbearing, Nursing, Loss of Blood or other fluids, Menstrual and other Diseases of Women, abuse of Alcohol, Tobacco and Narcotics, Protracted Illness, etc.

PROF. KONN B. SAYRES, M. D., Demonstrator of Anatomy, Miami Medical College, Cincinnati, O.

"I am pleased to inform you that I have during about six months last past made a critical trial of your **Crystalline Phosphate,** in various cases of mal-nutrition, nervous prostration. atonic dyspepsia, insomnia and kindred derangements of the vital functions, which has demonstrated the fact that it is a preparation of *very great value.* I believe your representations concerning it are fully justified by actual and palpable results in my practice, and I very cheerfully recommend it, knowing that a fair trial will prove it worthy of the confidence of the profession.

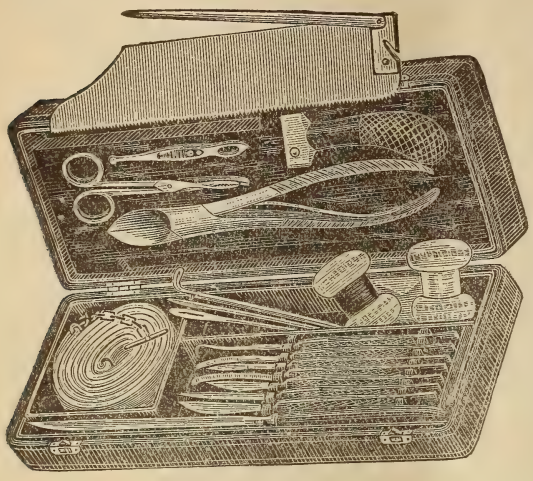
The Acutely Ill.

When a patient is acutely ill, the digestive powers share in the general condition, and consequently the food supplied should be of the most easily assimilable character. The predigestion of starchy matters outside the body, as in MELLIN'S FOOD, is necessary, and the soluble carbohydrates of which this food consists, soluble because predigested, form the true food of the acutely ill.—J. MILNER FOTHERGILL, M.D., Edin.

A sample of MELLIN'S FOOD *will be sent to any physician, free of expense, upon application.*

Doliber-Goodale Co., Boston, Mass.

LENTZ'S ASEPTIC COMPACT OPERATING SET, No. 10.



We have from time to time made improvements to this set and are now making a perfect aseptic set, which offers especial facilities for aseptic precautions; the blades are soldered into hollow German-silver handles nickel-plated, are light so as not to be unwieldy and admit of a firm grasp when operating.

The saw is adjusted to the handle on an entirely new principle, being made to separate easily and to facilitate thorough cleansing.

The handle is entirely of metal and fenestrated to overcome unnecessary weight.

Scissors and Forceps having French locks can be separated, and the slide can be easily removed from Artery and Needle Forceps.

Therefore, no opportunity is offered for the lodgment and development of germs.

The entire set is patterned with especial reference to facility in cleansing.

The instruments can be sterilized by placing them in boiling water, without fear of damaging them. Wood or rubber handles will not admit of this procedure. For price, see case A.

The following instruments are put up in either a fine Mahogany or Morocco case, with nickel trimmings, lined with velvet, and has an extra space for Trephine with handle, and Elevator if desired.

One Amputating Knife (6 in. blade); One Finger Knife; One Hernia Knife; One Sharp Curved Bistoury; Two Scalpels; One Tenotome; One Tenaculum; One Pair Scissors, curved or flat; One Saw (9 in. blade); One Liston's Bone Forceps, with Spring; One Artery and Needle Forceps, improved; One Esmarch's Flat Rubber Tourniquet, with Chain; One Hæmostatic Forceps; One Director, with Aneurism Needle; Two Silver Probes; Silk, Wire, Wax and Needles.

With the Sixteen Instruments Contained in this Case, any Ordinary Operation may be Performed.

SIZE, 11 INCHES LONG, 4 INCHES WIDE, 2 INCHES HIGH.

A.—German Silver aseptic Handles on Knives and Saw, ... $34 00
B.—Hard Rubber aseptic Handles on Knives and Saw, ... 29 00
C.—Ebony Handles on Knives and Saw (as shown in illustration), ... 25 00
Either Set, with Trephine and Elevator in addition, ... 4 65

DISCOUNT 25 PER CENT. TO PHYSICIANS. Our Catalogue of 260 pages will be sent on receipt of 10 cts. for postage

CHARLES LENTZ & SONS, Manufacturers of Surgical and Orthopædic Apparatus,

Established 1866. 18 North Eleventh Street, Philadelphia.

A Phosphorized Cerebro-Spinant

(FRELIGH'S TONIC).

FORMULA.

Ten minims of the Tonic contain the equivalents (according to the formulæ of the U. S. P., and Dispensatory) of

Tinct. Nux Strychnos,	1 minim.
" Ignatia Amara,	1 "
" Cinchona,	4 "
" Matricaria,	1 "
" Gentian,	½ "
" Columbo,	½ "
" Phosphorus, C. P.,	1-300 gr.
Aromatics,	2 minims.

Dose: 5 to 10 drops in 2 tablespoonfuls of water.

INDICATIONS.

Paralysis, Neurasthenia, Sick and Nervous Headache, Dyspepsia, Epilepsy, Locomotor Ataxia, Insomnia, Debility of Old Age, and in the Treatment of Mental and Nervous Diseases.

A BALTIMORE PHYSICIAN, WHOSE DIPLOMA DATES FROM 1825, SAYS:

"Your combination I find vastly more effective than any tonic I have ever used. It furnishes a most powerful evidence of the vastly increased power of medicament by combination and judicious pharmaceutic preparation."

Price, One Dollar per Bottle, containing 100 of the Average 5-Drop Doses.—Physicians' single sample delivered, charges prepaid, on application. That every physician may be his own judge of its value, irrespective of the opinions of others, we make the following

SPECIAL OFFER:

We will send to any physician, delivered, charges prepaid, on receipt of twenty-five cents, and his card or letter-head, half a dozen physicians' samples, sufficient to test it on as many cases for a week to ten days each. The Tonic is kept in stock regularly by all the leading wholesale druggists of the country. As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-lists, etc., address,

RABUTEAU'S DRAGEES OF IRON

Laureate of the Institute of France.—Prize in Therapeutics.

The studies made by the Physicians of the Hospitals have demonstrated that the **Genuine Dragees of Iron of Rabuteau** are superior to all other preparations of Iron in cases of *Chlorosis, Anæmia, Leucorrhœa, Debility, Exhaustion, Convalescence, Weakness of Children*, and the maladies caused by the Impoverishment and Alteration of the blood after periods of fatigue, watching, and excesses of any kind.

TAKE 4 TO 6 DRAGEES DAILY.

Rabuteau's Elixir of Iron is recommended to those persons who may be unable to swallow the Dragees. Dose —*A small wineglassful with meals.*

Rabuteau's Syrup of Iron is specially designed for children. Chalybeate medication, by means of **Rabuteau's Iron,** is the most economical and the most rational known to therapeutics.

No constipation, no diarrhœa, complete assimilation.

Take only the GENUINE IRON OF RABUTEAU of

CLIN & CO., Paris.

SOLUTION OF THE SALICYLATE OF SODA OF DOCTOR CLIN.

Laureate of the Paris Faculty of Medicine (MONTYON PRIZE).

Dr. Clin's Solution, always identical in its composition, and of an agreeable taste, permits the easy administration of *pure Salicylate of Soda*, and the variation of the dose in accordance with the indications presented.

"The *Salicylate of Soda* used by **Clin** is of perfect purity, "and is prepared with the greatest care; it is a medicament "in which we may have every confidence."

—*Paris Society of Medicine, Meeting of Feb. 8th, 1879.*

Clin's Solution, very exactly mixed, contains: 2 grammes of *Salicylate of Soda* per tablespoonful, 50 centigrammes of *Salicylate of Soda* per teaspoonful.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the three Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux,* Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic,* is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence,* having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PARIS.—22 RUE DROUOT.—PARIS.

PHILADELPHIA

This institution, in addition to complete arrangements for the treatment of Nervous Diseases by rest, electricity, massage, etc., under comfortable surroundings, is specially equipped for the treatment of cases of Fibroid Tumors and other intractable diseases of the pelvic viscera, by the conservative use of strong electric currents. For particulars, address

DR. G. BETTON MASSEY
1706 Walnut Street, Philadelphia

ONEITA

The perfection of table waters, with mineral properties unsurpassed in the treatment of Dyspepsia, Kidney and Liver troubles, Gout, Rheumatism, etc. The analysis of the spring shows a combination of mineral virtues unequaled in any other water. The water has been before the public but a short time, yet in that time has won public favor to a marked degree. Send for analysis of C. F. Chandler, Ph. D.

ONEITA SPRING CO.,
UTICA, N. Y.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

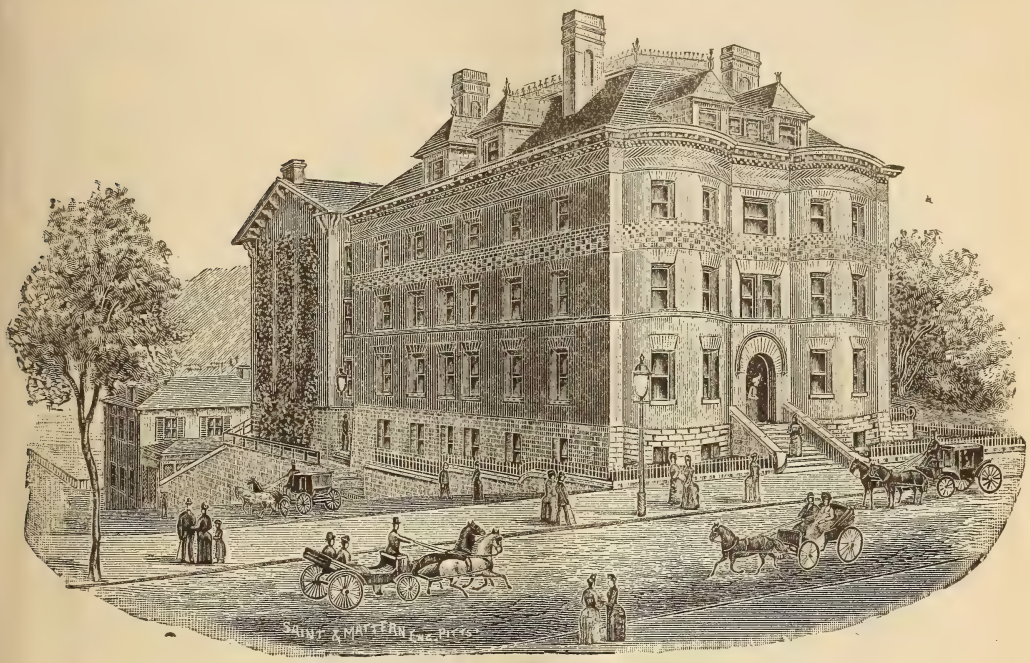
DR. R. S. SUTTON'S

Sanatorium for Diseases of Women.



Seventh Year Opens September 1, 1889.

ALLEGHENY CITY, PA.

This Institution is located on high ground, and overlooks the Allegheny, Monongahela and Ohio rivers; it commands a view of the city of Pittsburgh, and its picturesque surroundings. The building is large and beautiful, it is provided with every modern convenience, the halls are heated by steam, the rooms are commodious, well lighted and ventilated, and heated by open grates. The house is provided with a private parlor and reading-room for patients. The dining-room is large, handsomely finished, and furnished with small tables, securing privacy at meals for those who do not care to have meals served in their own rooms. Patients can be as secluded, should they desire it, as in a well appointed hotel. Each patient is examined by Dr. Sutton, and receives his daily personal attention, while Dr. J. H. Williamson, a physician of ample hospital experience, resides in the Institution, and has, under Dr. Sutton, the immediate care of the patients. The Institution accommodates 25 patients, and is equal in comfort to the best hotels.

Electricity, baths, douches, massage, local treatment, general medication and surgical operations are resorted to according to the requirements of each patient.

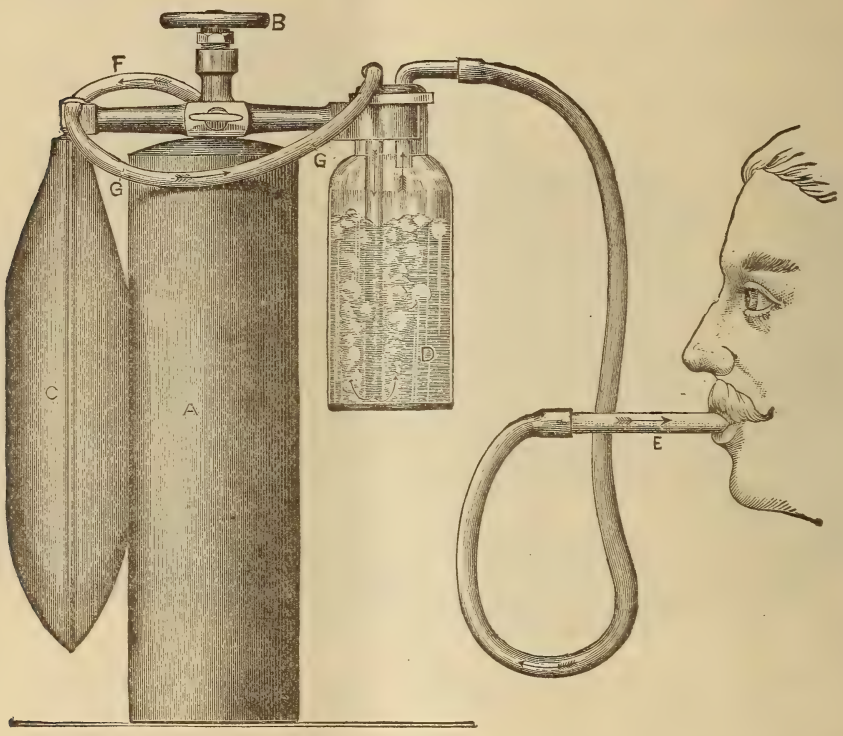
INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request:

Geo Hamlin Pres't Chas Roome Parmele Treas.

GENTLEMEN:

The Case of your wines sent me for analysis by Dr. A. L. Hummel, of the "Annals of Hygiene," containing specimens of your La Rosa Zinfandel, Mataro, Riesling, Royal Tokay, and Royal Grape Brandy, has been duly received.

I have examined them for the common contaminants of wine; to wit: Sulphurous acid and sulphites, salicylic acid, fuchsin, lead salts, etc., none of which I found present therein.

I have also determined their alcoholic strength, extractives, and ashes, and found them to correspond strictly in this respect with the standard of pure and natural wines, which cannot be said of many of the imported wines.

As a native of a wine-producing country, I consider myself somewhat of a judge of wines, and regard your products as comparing more than favorably with most of the wines from abroad which are sold at higher prices, so much so that I enclose within my order for fifty bottles of La Rosa Zinfandel, which I expect to use hereafter exclusively at my table.

Very Respectfully,

L. WOLFF, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

Apollinaris

"THE QUEEN OF TABLE WATERS."

The filling at the Apollinaris Spring (Rhenish Prussia), amounted to

11,894,000 BOTTLES IN **1887,**
12,720,000 BOTTLES IN **1888** AND
15,822,000 BOTTLES IN **1889.**

"The annual consumption of this favorite beverage affords a striking proof of the widespread demand which exists for table water of absolute purity, and it is satisfactory to find that, wherever one travels, in either hemisphere, it is to be met with; it is ubiquitous, and should be known as the cosmopolitan table water. 'Quod ab omnibus, quod ubique.'"—BRITISH MEDICAL JOURNAL.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

THE VALUE OF NUTRITION IN DISEASE.

All physicians who have ever used Murdock's Liquid Food and Suppositories recognize their value over all other foods, in breaking up disease and building up the patients after disease, preventing a relapse, **as the same results are obtained as in surgery.** Its value in surgical cases we illustrate by the records of the different cities and of Murdock's Free Surgical Hospital for Women, which is the largest in the United States. It contains 114 beds, every bed free, including operation, the operations ranging from 1000 to 1200 yearly, representing 90 of the worst classes known in surgery. Among these cases we have had **Cancer of uterus** (*Kolpo-hysterectomy*), 13; **Salpingitis** (*Tait's operation*), 31; **Fibroid of uterus** (*abdominal hysterectomy*), 19; **Ventral operation, hernia,** (*abdominal section*), 12; **Cancer of bowel** (*incision*), 2; **Parovarian cyst, 6; Papillomatous cyst** (*extirpation*), 4; **Tubercular peritonitis** (*incision*), 1, **Ovarian cystoma 27; Nymphomania** (*Battey*), 1; **Exploratory abdominal incisions, 12; Fibroid with abdominal abscess** (*Hegar*), 2; **Hysterorraphy, 2; Dermoid cyst, 3; Cirrhotic ovaries,** (*Battey*), 4; **Fibroid uterus** (*Hegar*), 6; **Hystero-epilepsy** (*Battey*), 1; **Haemato-Salpinx** (*Tait*), 5; **Rupture of intestine into vagina, 1; Dislocated kidney, 2; Fibroid tumor abdominal wall, 1; Resection of intestine** (*Senn*), 1; **Ruptured perineum, 294.** Patients are in the Hospital 8 days before and 26 days after operation, on an average.

In Boston, last year, 42 deaths were from Cancer in the Breast. In Murdock's Hospital, 35 such cases were operated on without a death, the patients remaining in the Hospital, on an average, 18 days.

Mortality in Boston,	25.60	per	1000.
" of Women in Boston,	29,00	"	"
" in **Murdock's Free Surgical Hospital,**	**5.00**	"	"
" New York,	26.32	"	"
" Philadelphia,	20.00	"	"
" Chicago,	20.90	"	"
" St. Louis,	20.49	"	"

showing our mortality is only one-sixth as great as of those in health. As good results were obtained in our General Hospital, which we kept open 27 months, **thus showing the value of nutrition as found in Murdock's Liquid Food, and so recognized by the British and American Medical Associations,** before which essays were read and discussed, and it is the only Raw food preparation on which essays were ever read.

Physicians are invited to visit our Hospitals and Works, also to send in patients and to be present at the operations. For any physician who has not used our Liquid Food (and Suppositories for adults and infants), we will deliver free samples to any express company in Boston.

When babies do not thrive, never change their food, but add five or more drops at each feeding of Murdock's Liquid Food, and their lost or needed vitality will be restored in less than thirty days. It is invaluable when weaning babies or when teething. If mothers will take one teaspoonful to a tablespoonful before each meal and on retiring, they will receive as much benefit as the baby.

Murdock Liquid Food Co., Boston.

GARDNER'S

SYRUP OF HYDRIODIC ACID,

Introduced in 1878 by R. W. GARDNER.

The Reputation which Hydriodic Acid has Attained During the past Eleven Years was Won by this Preparation.

Numerous Imitations prepared differently, and weaker in Iodine, are offered, from the use of which the same therapeutic effects cannot be obtained.

Caution.—Use no Syrup of Hydriodic Acid which has turned red. This shows decomposition and free Iodine. In this state it acts as an irritant and fails to produce desirable results.

Unprincipled apothecaries substitute imitations when Gardner's Syrup is prescribed, and physicians, failing to get desirable and promised results, attribute the fault, unjustly, to Gardner's Syrup.

THERAPEUTIC INDICATIONS.

Hay Fever; Rose Cold; Poisoning by Lead, Mercury or Arsenic; Acute and Chronic Rheumatism; Asthma; Chronic Bronchitis; Catarrh; Congestion of Lungs in Children; Adenitis; Eczema; Lupus; Chronic Malarial Poisoning; Lumbago; Acute Pneumonia; Psoriasis; Scrofulous Diseases; Goitre; Enlarged Glands; Cold Abscesses; Indolent Sores; Excessive Fat; Fatty Degeneration of the Heart; to absorb non-malignant Tumors; and in the latter stages of Syphilis; Syphilitic Phthisis.

Details of treatment furnished physicians upon application to undersigned without charge.

Gardner's Chemically Pure Syrups of Hypophosphites.

Embracing the separate Syrups of Lime, of Soda, of Iron, of Potassa, of Manganese, and an Elixir of the Quinia Salt; enabling physicians to accurately follow Dr. Churchill's method, by which thousands of authenticated cases of Phthisis have been cured. The only salts, however, used by Churchill in Phthisis are those of Lime, of Soda, and of Quinia, and always separately according to indications,—never combined.

The reason for the use of single Salts is because of antagonistic action of the different bases, injurious and pathological action of Iron, Potassa, Manganese, etc., in this disease.

These facts have been demonstrated by thirty years' clinical experience in the treatment of this disease exclusively, by Dr. Churchill, who was the first to apply these remedies in Medical practice. Modified doses are also required in this disease; seven grains during twenty-four hours being the maximum dose in cases of Phthisis, because of increased susceptibility of the patient to their action, the danger of producing toxic symptoms (as hemorrhage, rapid softening of tubercular deposit, etc.), and the necessity that time be allowed the various functions to recuperate simultaneously; over-stimulation, by pushing the remedy, resulting in crisis and disaster.

A pamphlet of sixty-four pages, devoted to a full explanation of these details and others, such as contra-indicated remedies, indications for the use of each hypophosphite, reasons for the use of absolutely pure Salts, protected in Syrup from oxidation, etc., mailed to physicians without charge upon application to

R. W. GARDNER, 158 William St., N. Y. City.

W. H. SCHIEFFELIN & CO., Sole Wholesale Agents, New York.

CELERINA

NERVE TONIC, STIMULANT AND ANTISPASMODIC.

FORMULA.—Every Fluid Drachm represents FIVE grains EACH—Celery, Coca, Kola, Viburnum and Aromatics.

INDICATIONS.—Loss of Nerve-Power (so usual with Lawyers, Preachers, Writers and Business Men), Impotency, Spermatorrhea, Nervous Headache, Neuralgia, Paralysis, Hysteria, Opium Habit, Inebriety, Dyspepsia, and ALL LANGUID conditions of the System.

Indispensable to restore a patient after alcoholic excess.

DOSE.—One or two Teaspoonfuls three or more times a day, as directed by the Physician.

LIQUID IRON-RIO

Palatable and easily assimilated. Does not produce Nausea, nor irritate the Stomach. Does not Cause Headache, nor Constipate. Does not Stain the Teeth. It is so Acceptable to the Stomach that its Use is Admissible when all other forms of Iron would be rejected. Being so Readily Assimilable, it only requires a small Dose.

Each Fluid Drachm contains ONE GRAIN of Iron in a Pleasant and Digestible Form.

DOSE.—One or more Teaspoonfuls as indicated, during or after meals.

S. H. KENNEDY'S

CONCENTRATED EXTRACT OF

PINUS CANADENSIS

DARK. A NON-ALCOHOLIC LIQUID. WHITE.

A MOST VALUABLE NON-IRRITATING MUCOUS ASTRINGENT.

INDICATIONS.—Albuminuria, Diarrhea, Dysentery, Night-Sweats, Hemorrhages, Profuse Expectoration, Catarrh, Sore Throat, Leucorrhea, and other Vaginal Diseases, Piles, Sores, Ulcers, Burns, Scalds, Gonorrhea, Gleet, Etc.

When Used as an Injection, to Avoid Staining of Linen, the WHITE Pinus should be used.

RECOMMENDED BY PROMINENT EUROPEAN AND AMERICAN PHYSICIANS.

RIO CHEMICAL CO., St. Louis, Mo., U. S. A.

LONDON. PARIS. CALCUTTA. MONTREAL.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

E. FOUGERA & CO., 30 North William St., New York,

Sole Agents for the above Preparations.

Doctor, we offer You a complete solution of the Question of Infant Feeding.

It is universally conceded that Mother's Milk of good quality is the best nutriment for infants.

This is the nourishment that we enable nursing mothers to supply abundantly.

When our new preparation, NUTROLACTIS, is given to nursing mothers whose milk is scanty, although the breasts are almost entirely dry, it will in the course of two days, or three at farthest, so increase the quantity that there will be milk enough to completely nourish a vigorous infant; the quality of the milk will be good, and at the same time the health and strength of the mother will be improved.

If the quantity of a mother's milk be adequate but the quality poor, lacking in nutritive elements, the use of this remedy will quickly and notably improve the quality and maintain the quantity until the end of normal lactation.

Physicians are assured that its use is always perfectly harmless.

Formula, Galega officinalis, G. Apolinea, G. Tephrosia. See Stillé & Maisch's National Dispensatory.

ESTABLISHED 1855.

DRS. STRONG'S SANITARIUM,

SARATOGA SPRINGS, NEW YORK,

Receives persons recommended to it by their home physicians for Treatment, Change, Rest or Recreation, and places them under well-regulated hygienic conditions so helpful in the treatment of chronic invalids or the overtaxed.

For Treatment: In addition to the ordinary remedial agents, it employs Turkish, Russian, Roman, Sulphur, Electro-Thermal, the French Douche (Charcot's), and all Hydropathic Baths; Vacuum Treatment, Swedish Movements Massage, Pneumatic Cabinet, Inhalations of Medicated, Compressed, and Rarefied Air, Electricity in various forms, Thermo-Cautery, Calisthenics, and Saratoga Waters, under the direction of a staff of educated physicians.

For Change: This Institution is located in a phenomenally dry, tonic, and quiet atmosphere, in the lower arc of the Adirondack Zone, and within the "Snow Belt."

For Rest: The Institution offers a well-regulated, quiet home, heated by steam and thoroughly ventilated, with cheering influences and avoiding the depressing atmosphere of invalidism.

For Recreation: To prevent introspection, are household sports at all seasons of the year, and in Winter, tobogganning, elegant sleighing, etc.; in Summer, croquet, lawn-tennis, etc.

Private professional references furnished upon application. Physicians are invited to inspect the Institution at their convenience. A liberal discount to physicians and their families.

For further information, address,

DRS. S. S. & S. E. STRONG.

THE OLD STYLE discarded on account of pulling apart, while the elastic is still in good condition.

THE "MASTER" SURGICAL ELASTIC STOCKINGS

FOR VARICOSE VEINS, WEAK AND SWOLLEN JOINTS, DROPSY OF THE LIMBS, SPRAINS, etc.

PROVIDED WITH

THE PATENT NON-ELASTIC STAYS AND ADJUSTING LOOPS,

By the aid of which they can be drawn on easily, like pulling on a boot. They will last much longer than the old style, as the stays prevent them from being torn apart in drawing them on.

WESTERN PENNSYLVANIA MEDICAL COLLEGE

CITY OF PITTSBURGH.

SESSIONS OF 1889—90.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. J. W. J. McKENNAN.

Business correspondence should be addressed to
PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

GENUINE BLAUD'S PILLS.

These pills, which have been inserted in the new French Pharmacopœia, have been employed with the greatest success for more than fifty years by most French and foreign physicians, to cure anemia, chlorosis, and all chlorotic affections in which iron is indicated.

Here is the opinion of men most eminent in medical science who have employed them:

"For thirty-five years, in which I have practised medicine, I have recognized the incontestable advantages of BLAUD'S PILLS over all other ferruginous preparations, and I regard them as the best anti-chlorotic."—DR. DOUBLE, *Ex-President of the Academy of Medicine.*

"Of all the ferruginous preparations, which have given good results in the treatment of chlorotic affections, BLAUD'S PILLS appear to us to deserve to hold the first rank."—*Dictionnaire universel de médecine*, Vol. II, p. 99.

These pills, prepared according to the genuine formule of the originator, by his nephew, Aug. Bland, Pharmacist of the Faculty of Paris, are sold only in bottles of 200 pills and half bottles of 100 pills, at a cost of 5 and 3 francs ($1.00, and seventy-five cents), and never in smaller quantities. *See that his name is stamped on each pill.* PARIS, 8 RUE PAYENNE, and at every Pharmacy. (Beware of imitations.)

DETROIT COLLEGE OF MEDICINE.

SESSION 1889-90.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, Sept. 25, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins April 2d, 1890; and closes June 11th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

Gymnasium Department.

It has become a matter of record, that hereafter the **Gymnasium** in all its details will be one of the leading features of our business.

With the addition to our own valuable patents, those of the **A. J. Reach Company**, of Philadelphia, recently purchased by us, enables us to claim the most **extensive department** of **Gymnasium Appliances in the world.**

We have been encouraged in this **important** movement by the constantly increasing demand from **Colleges, Seminaries,** and other **Educational** Institutions for Gymnasium Supplies, and henceforth we shall devote special attention to furnishing **plans, specifications,** and **estimates** to such and for **private residences** as well, and solicit correspondence with all contemplating the introduction of gymnastics for any purpose.

The Peerless Pulley Weight, illustration of which appears on this page, is a most perfect appliance for the development of the **chest** and **arms,** adjustable to the height of *any* person, and in weight from five to thirty pounds. For **man or woman** this is the peer of any method yet devised, especially for home use. Realizing the attention the **medical profession** and the **teacher,** are now giving to **healthful** exercise in **schools,** we solicit also their correspondence, and any orders, or business prceeding from such, will be gratefully received, and entitled to our best rates of discount, and will receive prompt and careful attention.

Visitors to our different establishments at **Chicago, New York,** and **Philadelphia** will always be welcome and politely served by the many efficient salesmen constantly in attendance.

ESTABLISHED 16 YEARS. BEWARE OF IMITATIONS.

COLDEN'S LIQUID BEEF TONIC

AN INVALUABLE AID IN MEDICAL PRACTICE

ORIGINAL | COLDEN'S LIEBIG'S LIQUID EXTRACT OF BEEF AND TONIC INVIGORATOR. | LABEL.

ESSENTIALLY DIFFERENT FROM ALL OTHER BEEF TONICS. UNIVERSALLY ENDORSED BY LEADING PHYSICIANS.

This preparation, consisting of the Extract of Beef (prepared by Baron Liebig's process), the best Brandy obtainable, soluble Citrate of Iron, Cinchona and Gentian is offered to the Medical Profession upon its own merits. It is of inestimable value in the treatment of **Debility, Convalescence from Severe Illness Anæmia, Malarial Fever, Chlorosis, Incipient Consumption, Nervous Weakness,** and maladies requiring a Tonic and Nutrient. It is quickly absorbed by the Stomach and upper portion of the Alimentary Canal, and therefore finds its way into the circulation quite rapidly.

COLDEN'S LIQUID BEEF TONIC appeals to the judgment of intelligent Physicians in the treatment of

ALL CASES OF GENERAL DEBILITY.

By the urgent request of several eminent members of the medical profession, I have added to each wineglassful of this preparation two grains of Soluble Citrate of Iron, and which is designated on the label, "**With Iron, No. 1;**" while the same preparation, **Without Iron,** is designated on the label as "**No. 2.**"

In prescribing this preparation, physicians should be particular to mention "*COLDEN'S,*" viz., "*Ext. Carnis Fl. Comp.* (*Colden*)." A Sample of **COLDEN'S BEEF TONIC** will be sent free on application, to any physician (enclosing business card) in the United States. *Sold by druggists generally.*

C. N. CRITTENTON, General Agent, 115 Fulton St., New York.

GLENN'S SULPHUR SOAP.

BEWARE OF COUNTERFEITS.

Physicians know the great value of the local use of Sulphur in the **Treatment of Diseases of the Skin.**

Constantine's Pine-Tar Soap.

THE BEST SOAP MADE.

Has been on trial among physicians for very many years as a healing agent. **By far the Best Tar Soap made.**

Wholesale Depot, C. N. CRITTENTON, 115 Fulton St, New York.

Samples of above Soaps SENT FREE, on application, to any Physician enclosing card.

Address,

MEDICAL AND SURGICAL REPORTER,

P. O. Box 843, Philadelphia.

FELLOWS'
HYPO-PHOS-PHITES

(SYR: HYPOPHOS: COMP: FELLOWS)

Contains **The essential elements** to the Animal Organization—Potash and Lime.

The **Oxydizing Agents**—Iron and Manganese;

The **Tonics**—Quinine and Strychnine,

And the **Vitalizing Constituent**—Phosphorus,

Combined in the form of a Syrup, with *slight alkaline reaction.*

It Differs in Effect from all others, being pleasant to taste, acceptable to the stomach, and harmless under prolonged use.

It has Sustained a High Reputation in America and England for efficiency in the treatment of Pulmonary Tuberculosis, Chronic Bronchitis, and other affections of the respiratory organs, and is employed also in various nervous and debilitating diseases with success.

Its Curative Properties are largely attributable to Stimulant, Tonic, and Nutritive qualities, whereby the various organic functions are recruited.

In Cases where innervating constitutional treatment is applied, and tonic treatment is desirable, this preparation will be found to act with safety and satisfaction.

Its Action is Prompt; stimulating the appetite and the digestion, it promotes assimilation, and enters directly into the circulation with the food products.

The Prescribed Dose produces a feeling of buoyancy, removing depression or melancholy, and hence is of great value in the treatment of Mental and Nervous Affections.

From its exerting a double tonic effect and influencing a healthy flow of the secretions, its use is indicated in a wide range of diseases.

Prepared by JAMES I. FELLOWS, Chemist,

48 VESEY STREET, NEW YORK.

ANTIFEBRIN IN INFLUENZA!

This use of this Renowned ANTIPYRETIC, ANODYNE, SEDATIVE and NERVINE seems suggested by the following Judgments passed on it by Reputed Authorities in Symptomatically *Allied Complaints:*—

As an **Antifebrile** Dose:—2 to 4 grains *single;* 16 to 32 grains *daily.*—(WEINSTEIN, Vienna.)

As an **Anodyne** and **Nervine** Dose in severest Neurotic and Secondary Pains:—8 to 16 grains, *one to four times per day.*—(DEMIEVILLE, Lausanne.)

Mode of Administration:

"Even the *initial dose* gave evident relief; commonly within half an hour. If this did not suffice to break up the symptoms materially, a second dose followed in an hour or two; at the very utmost a third one was given the same day.

"The remedy was effective and well tolerated at all times; at all hours of the day; on an empty or a full stomach; even during menstruation.

"The form of exhibition was that of *powders*, wrapped in *wafers*. The readier solubility of the Antifebrin in Alcohol indicates the advisability of following the dose by a small draught of Wine or Brandy."—(OTT, Prague.)

ANOTHER MODE OF ADMINISTRATION:—*Dissolve* your Dose (4 to 12 grains) of **ANTIFEBRIN** in ½–1 ounce (1 to 2 Tablespoonfuls) of *Boiling Water*,—stirring for a minute or two, until dissolved. Allow the Solution *to cool down* to about 104 degrees F. (being just comfortably warm) and sweeten to taste, *Before Taking!*—NO ALCOHOL, WINE, or LIQUOR needed with it when thus prepared.

ANTIFEBRIN

was found **Superior** to the **Following** Remedies in **Efficacy**, or in **Safety**, or in **Both**:—

Antipyrine,—*Quinine*,—*Morphine*,—*Opium*,—CHLORAL HYDRATE—ACONITE,—CAFFEINE,—KAIRINE,—*Salicylic Acid*,—CARBOLIC ACID,—*Bromides*,—IODIDES.

Among the Medical Authorities from whose Clinical and other Published Reports the above-stated PREFERENCES OF ANTIFEBRIN OVER OTHER REMEDIES have been drawn, are the following:

HARE, University of Pennsylvania;—DUJARDIN-BEAUMETZ, Paris;—HERCZEL, Heidelberg;—MURRAY, *Brit. Med. Journal;*—PAVAIVAJNA, *Centralblatt für die gesammte Therapie;*—BARR, Bridgeport, Ill.;—KELL, Delphos, O.;—HAY, New York;—HAAS, Prague.

Antifebrin was also *found to be:*

"Thoroughly *reliable* as an ANTIPYRETIC."—(DEMME, Berne.)

"*Not only* powerfully ANTITHERMIC, but also a most *useful* NERVINE."—(LEPINE, Lyons.)

"A *powerful, safe*, and *certain* ANTITHERMIC agent."—(EVANS, Easton, Pa.)

"*Complete* ANALGETIC effect in nine cases out of every ten."—(FISCHER, Cannstatt.)

PHENACETINE-BAYER IN INFLUENZA.

We have just received advices that Phenacetine-Bayer is being used to advantage both in Russia and Germany, in the treatment of the present epidemic of **INFLUENZA.** It is also being extensively employed in America for the same purpose.

Dr. A. C. HALLAM, Brooklyn, N. Y., states :—"That he has used Phenacetine extensively in the present epidemic of Influenza and has been well pleased with its effects. The rapidity with which it relieves the muscular pains has been very gratifying to him, the patient breaking out in a profuse perspiration, and in a few hours seeming relieved of all but the catarrhal symptoms, which run on and call for other treatment."—*The New York Medical Journal,* Jan. 4, 1890.

221 GENESEE STREET, UTICA, N. Y., January 6, 1890.

To the Editor of the New York Medical Journal:

SIR: I desire to echo the statement made in your last issue by Dr. A. C. Hallam, of Brooklyn, viz.: That in the treatment of fifty cases of influenza I have used phenacetine in five-grain doses repeated hourly until fifteen grains had been taken, and in *every case* the severe muscular pains and headache disappeared; following this with five-grain doses, three times daily, of the salicylate of cinchonidine. The disease disappeared upon the fourth day, and in *no cases* have there been any sequelæ either of bronchitis or pneumonia. Phenacetine, I consider superior in every way to antipyrine and acetanilide.

CHARLES R. WEED, M. D.

Phenacetine-Bayer (Para-Acetphenetidine), prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, is supplied by us in one-ounce vials and also in the form of our soluble pills, containing two, four, and five grains each. Either form may be obtained of any reputable apothecary.

W. H. Schieffelin & Co.,
170 & 172 WILLIAM STREET,
NEW YORK.

SUCCUS ALTERANS

(McDADE.)

SUCCUS ALTERANS is a purely vegetable compound of the preserved juices of Stillingia Sylvatica Lappa Minor, Phytolacca Decandra, Smilax Sarsaparilla, and Xanthoxylum Carolinianum, as collected by Dr. Geo. W. McDade, exclusively for Eli Lilly & Co., and endorsed by Dr. J. Marion Sims.

SUCCUS ALTERANS continues to gain favor from its remarkable Alterative and Tonic properties, *eliminating specific poison from the blood* and *increasing the proportion of red corpuscles in anæmic patients* to a wonderful degree; is endorsed by the medical profession, and in use by many hospitals of note.

SUCCUS ALTERANS in venereal and cutaneous diseases is fast supplanting Mercury, the Iodides, and Arsenic; and is a certain remedy for Mercurialization, Iodism, and the dreadful effects often following the use of Arsenic in skin diseases.

SUCCUS ALTERANS is also strongly recommended for its Tonic and Alterative effects in myriad forms of scrofulous disease, and in all cases where anæmia is a factor. Such patients rapidly develop a good appetite, sleep soundly, and gain flesh rapidly. Many cases are on record where patients increased ten to twenty-five pounds in weight in a few weeks.

SUCCUS ALTERANS is giving satisfactory results in treatment of *Chronic Rheumatism*, and can be used with confidence.

SUCCUS ALTERANS may be given for any length of time, without injury to the patient.

SUCCUS ALTERANS is put up in pint round amber bottles, and *never in bulk.*

Send for copy of our Hand-Book of Pharmacy and Therapeutics. Useful for reference and contains much valuable information.

PIL. APHRODISIACA

(LILLY.)

Phosphorus and **Nux Vomica**, as is well known to the profession, act as powerful tonics to the nervous system, especially the spinal cord, and can be relied upon as possessing real aphrodisiac power. The **Damiana** used is the genuine **Turnera Aphrodisiaca.** By our process for the manufacture of **Phosphorus Pills**, a thorough subdivision of phosphorus in the mass is obtained, and, with a coat, ing perfectly **protecting** it from **oxidation**, there is nothing to be desired. It is necessary that the administration of this pill be continued from **three to four weeks**, or until the **system is thoroughly under the influence of the remedy.** It is indicated in **mental overwork, sexual debility, impotency.** It is decidedly beneficial in cases of **nocturnal emissions**, the result of excesses, **mental apathy**, or indifference, and in an **enfeebled condition of the general system**, with **weakness or dull pain in the lumbo sacral region.** In diseases of the **reproductive organs** of the female, and especially of the uterus, it is one of our most valuable agents, acting as a **uterine tonic**, and gradually removing abnormal conditions, while at the same time, it imparts tone and vigor; hence, it is of value in **Leucorrhea, Amenorrhea, Dysmenorrhea,** and to remove the tendency to repeated miscarriages.

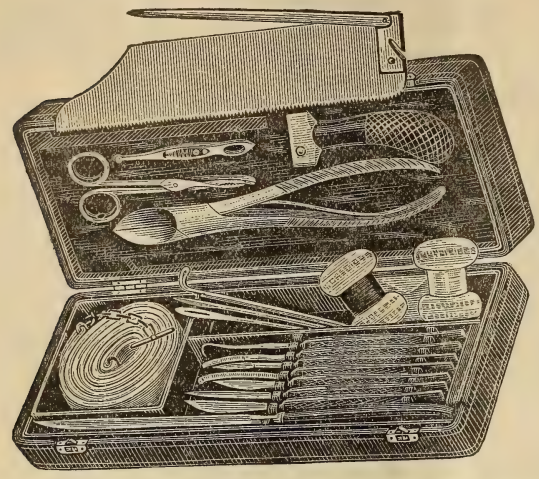
LENTZ'S ASEPTIC COMPACT OPERATING SET, No. 10.



We have from time to time made improvements to this set and are now making a perfect aseptic set, which offers especial facilities for aseptic precautions; the blades are soldered into hollow German-silver handles, nickel-plated, are light so as not to be unwieldy and admit of a firm grasp when operating.

The saw is adjusted to the handle on an entirely new principle, being made to separate easily and to facilitate thorough cleansing.

The handle is entirely of metal and fenestrated to overcome unnecessary weight.

Scissors and Forceps having French locks can be separated, and the slide can be easily removed from Artery and Needle Forceps.

Therefore, no opportunity is offered for the lodgment and development of germs.

The entire set is patterned with especial reference to facility in cleansing.

The instruments can be sterilized by placing them in boiling water, without fear of damaging them. Wood or rubber handles will not admit of this procedure. For price, see case A.

The following instruments are put up in either a fine Mahogany or Morocco case, with nickel trimmings, lined with velvet, and has an extra space for Trephine with handle, and Elevator if desired.

One Amputating Knife (6 in. blade); One Finger Knife; One Hernia Knife; One Sharp Curved Bistoury; Two Scalpels; One Tenotome; One Tenaculum; One Pair Scissors, curved or flat; One Saw (9 in. blade); One Liston's Bone Forceps, with Spring; One Artery and Needle Forceps, improved; One Esmarch's Flat Rubber Tourniquet, with Chain; One Hæmostatic Forceps; One Director, with Aneurism Needle; Two Silver Probes; Silk, Wire, Wax and Needles.

With the Sixteen Instruments Contained in this Case, any Ordinary Operation may be Performed.

SIZE, 11 INCHES LONG, 4 INCHES WIDE, 2 INCHES HIGH.

A.—German Silver aseptic Handles on Knives and Saw, ... $34 00
B.—Hard Rubber aseptic Handles on Knives and Saw, ... 29 00

Established 1866. **18 North Eleventh Street, Philadelphia.**

The Acutely Ill.

When a patient is acutely ill, the digestive powers share in the general condition, and consequently the food supplied should be of the most easily assimilable character. The predigestion of starchy matters outside the body, as in MELLIN'S FOOD, is necessary, and the soluble carbohydrates of which this food consists, soluble because predigested, form the true food of the acutely ill.—J. MILNER FOTHERGILL, M.D., Edin.

A sample of MELLIN'S FOOD *will be sent to any physician, free of expense, upon application.*

CLIN & CO.,—Paris.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the **three** Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

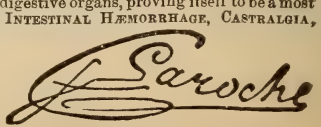
FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PARIS.—22 RUE DROUOT.—PARIS.



E. FOUGERA & CO., New York,

Sole Agents for the United States for the above Preparations.

Physicians visiting Philadelphia, are invited to call and inspect the new building of the

Philadelphia Lying-In Charity

At the Southwest Corner of Eleventh and Cherry Streets.

Handsome Wards and elegantly appointed **Private Rooms** are provided for the reception and care of maternity cases.

Private Rooms in an isolated portion of the building are also provided, for the treatment of **GYNECOLOGICAL CASES.**

All communications relative to the admission of patients should be made to

Dr. Charles Meigs Wilson, 126 North Eleventh Street, Philadelphia.

Prof. Loisette's
MEMORY
DISCOVERY AND TRAINING METHOD

In spite of adulterated imitations which miss the theory, and practical results of the Original, in spite of the grossest misrepresentations by envious would-be competitors, and in spite of "base attempts to rob" him of the fruit of his labors, (all of which demonstrate the undoubted superiority and popularity of his teaching), Prof. Loisette's Art of Never Forgetting is recognized to-day in both Hemispheres as marking an Epoch in Memory Culture. His Prospectus (sent post free) gives opinions of people in all parts of the globe who have actually studied his System by correspondence, showing that his System is *used only while being studied, not afterwards; that any book can be learned in a single reading, mind-wandering cured, &c.* For Prospectus, Terms and Testimonials address

Prof. A. LOISETTE, 237 Fifth Avenue, N.Y

THE OLD STYLE discarded on account of pulling apart, while the elastic is still in good condition.

THE
"MASTER" SURGICAL ELASTIC STOCKINGS

FOR VARICOSE VEINS, WEAK AND SWOLLEN JOINTS, DROPSY OF THE LIMBS, SPRAINS, etc.

PROVIDED WITH

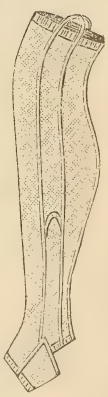
THE PATENT NON-ELASTIC STAYS AND ADJUSTING LOOPS,

By the aid of which they can be drawn on easily, like pulling on a boot. They will last much longer than the old style, as the stays prevent them from being torn apart in drawing them on.

ALL KINDS AND SIZES IN THREAD OR SILK ELASTIC. Made under D. Master's Patents, Nov. 29, 1881, March 21, 1882. Send for descriptive circular and price-list to

POMEROY TRUSS CO.,
785 Broadway, New York.

DANIEL POMEROY, Pres. CHARLES R. DEAN, Sec.



THE NEW STYLE cannot pull apart and consequently lasts until worn out.

ONEITA

The perfection of table waters, with mineral properties unsurpassed in the treatment of Dyspepsia, Kidney and Liver troubles, Gout, Rheumatism, etc. The analysis of the spring shows a combination of mineral virtues unequaled in any other water. The water has been before the public but a short time, yet in that time has won public favor to a marked degree. Send for analysis of C. F. Chandler, Ph. D.

ONEITA SPRING CO.,
UTICA, N. Y.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

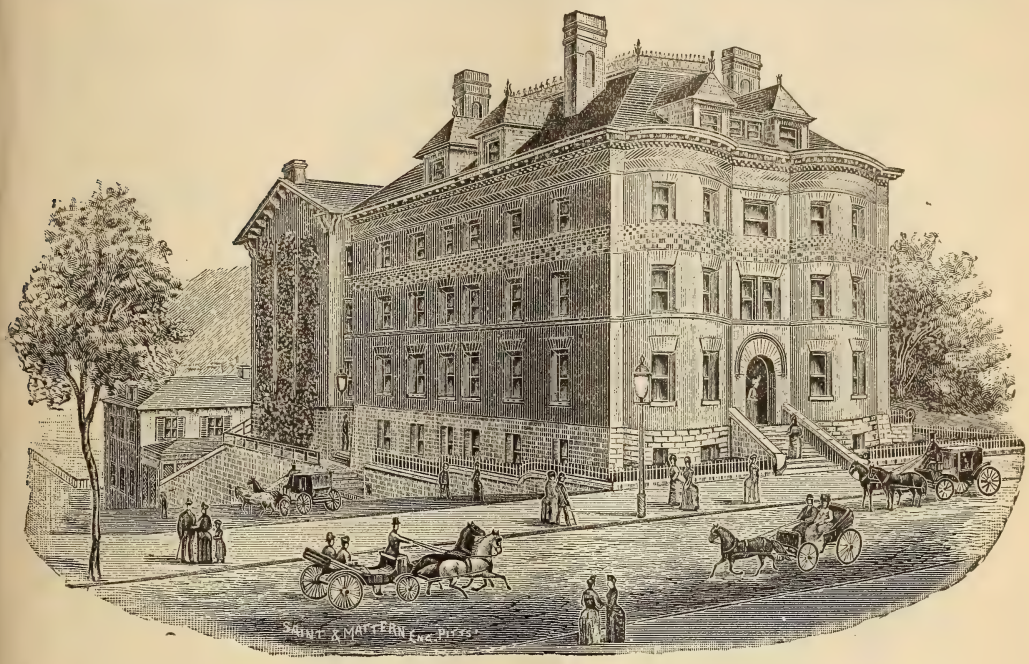
DR. R. S. SUTTON'S

Sanatorium for Diseases of Women.



Seventh Year Opens September 1, 1889.

ALLEGHENY CITY, PA.

This Institution is located on high ground, and overlooks the Allegheny, Monongahela and Ohio rivers; it commands a view of the city of Pittsburgh, and its picturesque surroundings. The building is large and beautiful, it is provided with every modern convenience, the halls are heated by steam, the rooms are commodious, well lighted and ventilated, and heated by open grates. The house is provided with a private parlor and reading-room for patients. The dining-room is large, handsomely finished, and furnished with small tables, securing privacy at meals for those who do not care to have meals served in their own rooms. Patients can be as secluded, should they desire it, as in a well appointed hotel. Each patient is examined by Dr. Sutton, and receives his daily personal attention, while Dr. J. H. Williamson, a physician of ample hospital experience, resides in the Institution, and has, under Dr. Sutton, the immediate care of the patients. The Institution accommodates 25 patients, and is equal in comfort to the best hotels.

Electricity, baths, douches, massage, local treatment, general medication and surgical operations are resorted to according to the requirements of each patient.

For further information address the Matron

MISS KENNEDY,

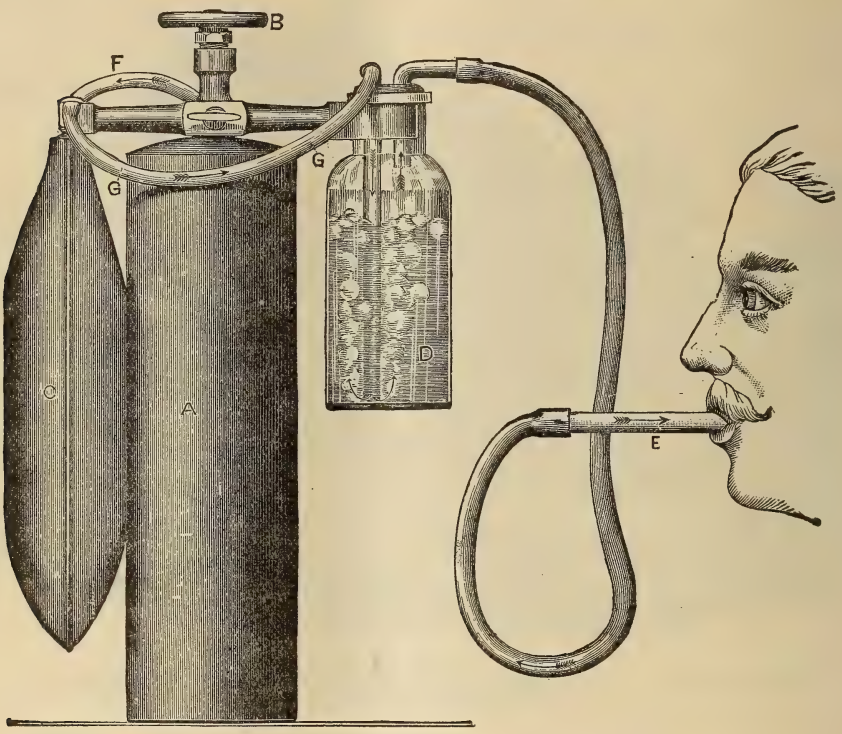
INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

PHILADELPHIA, NEW YORK, BOSTON, CHICAGO, BROOKLYN.

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request.

21 PARK PLACE N.Y.

Geo Hamlin Prest. Chas Roome Parmele Treas.

GENTLEMEN:

The Case of your wines sent me for analysis by Dr. A. L. Hummel, of the "Annals of Hygiene," containing specimens of your La Rosa Zinfandel, Mataro, Riesling, Royal Tokay, and Royal Grape Brandy, has been duly received.

I have examined them for the common contaminants of wine; to wit: Sulphurous acid and sulphites, salicylic acid, fuchsin, lead salts, etc., none of which I found present therein.

I have also determined their alcoholic strength, extractives, and ashes, and found them to correspond strictly in this respect with the standard of pure and natural wines, which cannot be said of many of the imported wines.

As a native of a wine-producing country, I consider myself somewhat of a judge of wines, and regard your products as comparing more than favorably with most of the wines from abroad which are sold at higher prices, so much so that I enclose within my order for fifty bottles of La Rosa Zinfandel, which I expect to use hereafter exclusively at my table.

Very Respectfully,

L. WOLFF, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

CEREBRAL EXHAUSTION

HORSFORD'S ACID PHOSPHATE.

It has been shown that the phosphates are found in excess in the urine in cases where the nerve centres (the brain and spinal cord) have been overworked, or subjected to undue labor, and the opinion is confirmed that there is a received relation between an excess of phosphates in the urine, and intellectual exercise.

This preparation supplies the phosphates and phosphoric acid, is readily assimilated, pleasant to the taste, and aids digestion.

Dr. S. A. HARVEY, Cheboygan, Mich., says:

"I have used it with marked benefit, in several cases of cerebral irritation."

Send for descriptive circular. Physicians who wish to test it will be furnished a bottle on application, without expense, except express charges.

Prepared under the direction of Prof. E. N. HORSFORD, by the

Rumford Chemical Works, Providence, R. I.

Beware of Substitutes and Imitations.

CAUTION:—Be sure the word "HORSFORD'S" is printed on the label. All others are spurious. Never sold in bulk.

A Phosphorized Cerebro-Spinant

(FRELIGH'S TONIC).

FORMULA.

Ten minims of the Tonic contain the equivalents (according to the formulæ of the U. S. P., and Dispensatory) of

Tinct. Nux Strychnos,	1	minim.
" Ignatia Amara,	1	"
" Cinchona,	4	"
" Matricaria,	1	"
" Gentian,	½	"
" Columbo,	½	"
" Phosphorus, C. P.,	1-300	gr.
Aromatics,	2	minims.

Dose: 5 to 10 drops in 2 tablespoonfuls of water.

INDICATIONS.

Paralysis, Neurasthenia, Sick and Nervous Headache, Dyspepsia, Epilepsy, Locomotor Ataxia, Insomnia, Debility of Old Age, and in the Treatment of Mental and Nervous Diseases.

A BALTIMORE PHYSICIAN, WHOSE DIPLOMA DATES FROM 1825, SAYS:

"Your combination I find vastly more effective than any tonic I have ever used. It furnishes a most powerful evidence of the vastly increased power of medicament by combination and judicious pharmaceutic preparation."

Price, One Dollar per Bottle, containing 100 of the Average 5-Drop Doses.—Physicians' single sample delivered, charges prepaid, on application. That every physician may be his own judge of its value, irrespective of the opinions of others, we make the following

SPECIAL OFFER:

We will send to any physician, delivered, charges prepaid, on receipt of twenty-five cents, and his card or letter-head, half a dozen physicians' samples, sufficient to test it on as many cases for a week to ten days each. The Tonic is kept in stock regularly by all the leading wholesale druggists of the country. As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-lists, etc., address,

I. O. WOODRUFF & CO.,

Manufacturers of Physicians' Specialties,

Apollinaris

"THE QUEEN OF TABLE WATERS."

The filling at the Apollinaris Spring (Rhenish Prussia), amounted to

11,894,000 BOTTLES IN **1887,**
12,720,000 BOTTLES IN **1888** AND
15,822,000 BOTTLES IN **1889.**

"The annual consumption of this favorite beverage affords a striking proof of the widespread demand which exists for table water of absolute purity, and it is satisfactory to find that, wherever one travels, in either hemisphere, it is to be met with; it is ubiquitous, and should be known as the cosmopolitan table water. 'Quod ab omnibus, quod ubique.'"—BRITISH MEDICAL JOURNAL.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

THE VALUE OF NUTRITION IN DISEASE.

All physicians who have ever used Murdock's Liquid Food and Suppositories recognize their value over all other foods, in breaking up disease and building up the patients after disease, preventing a relapse, **as the same results are obtained as in surgery.** Its value in surgical cases we illustrate by the records of the different cities and of Murdock's Free Surgical Hospital for Women, which is the largest in the United States. It contains 114 beds, every bed free, including operation, the operations ranging from 1000 to 1200 yearly, representing 90 of the worst classes known in surgery. Among these cases we have had **Cancer of uterus** (*Kolpo-hysterectomy*), 13; **Salpingitis** (*Tait's operation*), 31; **Fibroid of uterus** (*abdominal hysterectomy*), 19; **Ventral operation, hernia,** (*abdominal section*), 12; **Cancer of bowel** (*incision*), 2; **Parovarian cyst, 6; Papillomatous cyst** (*extirpation*), 4; **Tubercular peritonitis** (*incision*), 1, **Ovarian cystoma 27; Nymphomania** (*Battey*), 1; **Exploratory abdominal incisions, 12; Fibroid with abdominal abscess** (*Hegar*), 2; **Hysterorraphy, 2; Dermoid cyst, 3; Cirrhotic ovaries,** (*Battey*), 4; **Fibroid uterus** (*Hegar*), 6; **Hystero-epilepsy** (*Battey*), 1; **Haemato-Salpinx** (*Tait*), 5; **Rupture of intestine into vagina, 1; Dislocated kidney, 2; Fibroid tumor abdominal wall, 1; Resection of intestine** (*Senn*), 1; **Ruptured perineum, 294.** Patients are in the Hospital 8 days before and 26 days after operation, on an average.

In Boston, last year, 42 deaths were from Cancer in the Breast. In Murdock's Hospital, 35 such cases were operated on without a death, the patients remaining in the Hospital, on an average, 18 days.

Mortality in Boston,	25.60	per	1000.
" of Women in Boston,	29,00	"	"
" in **Murdock's Free Surgical Hospital,**	**5.00**	"	"
" New York,	26.32	"	"
" Philadelphia,	20.00	"	"
" Chicago,	20.90	"	"
" St. Louis,	20.49	"	"

showing our mortality is only one-sixth as great as of those in health. As good results were obtained in our General Hospital, which we kept open 27 months, **thus showing the value of nutrition as found in Murdock's Liquid Food, and so recognized by the British and American Medical Associations,** before which essays were read and discussed, and it is the only Raw food preparation on which essays were ever read.

Physicians are invited to visit our Hospitals and Works, also to send in patients and to be present at the operations. For any physician who has not used our Liquid Food (and Suppositories for adults and infants), we will deliver free samples to any express company in Boston.

When babies do not thrive, never change their food, but add five or more drops at each feeding of Murdock's Liquid Food, and their lost or needed vitality will be restored in less than thirty days. It is invaluable when weaning babies or when teething. If mothers will take one teaspoonful to a tablespoonful before each meal and on retiring, they will receive as much benefit as the baby.

Murdock Liquid Food Co., Boston.

GOUDRON DE BLOUNT

PREPARED FROM THE GENUINE CAROLINA TAR.

DOSE.—One fluid drachm four or more times a day (as indicated), either full strength, diluted, or, in combination.

INDICATIONS.—Chronic and acute affections of the Air Passages, Coughs, Colds, Bronchitis, Asthma and Consumption.

WILLIAM MURRELL, M.D., F.R.C.P.,

Lecturer on Pharmacology and Therapeutics at the Westminster Hospital; Examiner in Materia Medica to the Royal College of Physicians of London; Fellow of the Medico-Chirurgical College of Philadelphia,

Says:—"I have used with success 'Goudron de Blount.' The results have been good, and the preparation is popular with patients."

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.

Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N.Y.

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

Nerve-Counterfeits of Uterine Disease.

Dr. Wm. Goodell, the well-known Professor of Gynecology, Univ. Penn., Philadelphia, says:

"*The symptoms of nerve-prostration so greatly resemble those of even coarse uterine lesions* that the nerve-mimicries can very readily be mistaken for signals of actual organic disease. Nor, indeed, are they always distinguishable the one from the other, for the marvelous kinship between mind and matter is a tangled skein, not yet unraveled by dead-house or by laboratory.

"What, then, are these symptoms? Their name is legion, but the most common ones are, strangely enough, those which lay and professional tradition, with singular consent, have labeled as the symptoms *par excellence* of womb disease. They are, in the order of their frequency, great weariness, more or less of nervousness and of wakefulness; inability to walk any distance, and a bearing-down feeling; headache, nape-ache, and backache; cold feet, an irritable bladder, spinal tenderness, and pain in one ovary, usually the left, or in both ovaries. The sense of exhaustion is a remarkable one; the woman is always tired; she passes the day tired, she goes to bed tired, and she wakes up tired, often, indeed, more tired than when she fell asleep. She sighs a great deal, and her arms and legs tremble or 'fall asleep' so frequently that she fears palsy or paralysis.

"Other symptoms, not quite so common, are the cerebral ones, such as low spirits, bad dreams, nightmares, and night-terrors; explosive sounds in the head, a loss of memory, suicidal thoughts, the fear of impending insanity, the dread of being left alone, or of being in a crowd.

"From a large experience I humbly offer to the reader the following watchwords as broad helps to diagnosis:

"*First.* Always bear in mind what another has pithily said, that 'woman has some organs outside of the pelvis.'

"*Secondly.* Each neurotic case will usually have a tale of fret or grief, of cark and care, of wear and tear.

"*Thirdly.* Scant or delayed or suppressed menstruation is far more frequently the result of nerve-exhaustion than of uterine disease.

"*Fourthly.* Anteflexion *per se* is not a pathological condition. It is so when associated with sterility or with painful menstruation, and only then does it need treatment.

"*Fifthly.* An irritable bladder is more often a nerve symptom than a uterine one.

"*Sixthly.* In a large number of cases of supposed or of actual uterine disease which display marked gastric disturbance, if the tongue be clean, the essential disease will be found to be neurotic; and it must be treated so.

"*Seventhly.* Almost every supposed uterine case, characterized by excess of sensibility and by scantiness of will-power, is essentially a neurosis.

"*Eighthly.* In the vast majority of cases in which the woman takes to her bed and stays there indefinitely, from some supposed uterine lesion, she is bed-ridden from her brain and not from her womb. I will go further, and assert that this will be the rule even when the womb itself is displaced, or it is discovered by a disease or by a lesion that is not in itself exacting or dangerous to life.

"*Finally.* Uterine symptoms are not *always* present in cases of uterine disease. Nor when present, and even urgent, do they *necessarily* come from uterine disease, for they may be merely nerve-counterfeits of uterine disease."

The best remedial agent for the above nerve troubles, so well described by Prof. Goodell, is that well-known remedy, CELERINA (Rio), in teaspoonful doses thrice daily. Where uterine disease is also suspected, the best prescription, as largely attested by the profession, is

℞ Celerina (Rio), ... 4 ounces.
Aletris Cordial (Rio), . . . 4 ounces.
M. Sig.: Teaspoonful four times a day.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

Permanent Pepsin.

THE INSEPARABLE STANDARDS OF VALUE ARE PERMANENCY AND ACTIVITY.

WHEN a physician prescribes pepsin and his patient finds that it "sticks to the paper," that it forms a gummy mass "in powders," he may rely upon it that FAIRCHILD'S PEPSIN has not been dispensed; if he has ordered Fairchild's, this behavior is positive evidence that he and his patient have been the victims of "substitution."

Pepsins which are hygroscopic, which do undergo upon exposure to air the changes characteristic of peptone, are offered (in the form of scales and in powder) with pretensions to permanent quality.

If a product is sought, of well-proven permanency and of highest standard of activity, FAIRCHILD'S PEPSIN is the one which will never give cause for complaint.

Fairchild's was the original "Scale Pepsin;" the first positively "free from starch, sugar, acid, peptones or any added substance." The host of imitations of "Scale Pepsin" bear witness to the value and reputation of the original.

UNIVERSITY OF PENNSYLVANIA.—Medical Department.

The 124TH ANNUAL WINTER SESSION began Tuesday, October 1st, 1889, at 12 M., and will continue until May 1st, 1890.
The PRELIMINARY SESSION began September 18th, 1889.
The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology, with Bedside Instruction in Medicine, Surgery and Gynecology are a part of the regular course and without additional expense.

FACULTY.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
D. HAYES AGNEW, M.D., LL.D., Honorary Professor of Clinical Surgery.
WILLIAM PEPPER, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
WILLIAM GOODELL, M.D., Professor of Gynecology.
JAMES TYSON, M.D., Professor of Clinical Medicine.
HORATIO C. WOOD, M.D., LL.D., Professor of Materia Medica, Pharmacy and General Therapeutics.
THEODORE G. WORMLEY, M.D., LL.D., Professor of Chemistry and Toxicology.
JOHN ASHHURST, JR., M.D., Professor of Surgery and of Clinical Surgery.
EDWARD T. REICHERT, M.D., Professor of Physiology.
WILLIAM F. NORRIS, M.D., Honorary Prof. of Ophthalmology
BARTON COOKE HIRST, M.D., Professor of Obstetrics.
J. WILLIAM WHITE, M.D., Professor of Clinical Surgery.
JOHN GUITÉRAS M.D., Professor of General Pathology and Morbid Anatomy.
GEORGE A. PIERSOL, M.D., Professor of Histology and Embryology.
SAMUEL G. DIXON, M.D., Professor of Hygiene.

WESTERN PENNSYLVANIA MEDICAL COLLEGE

CITY OF PITTSBURGH.

SESSIONS OF 1889—90.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. J. W. J. McKENNAN.

Business correspondence should be addressed to
PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

NATIONAL MEDICAL COLLEGE.

MEDICAL DEPARTMENT OF THE

COLUMBIAN UNIVERSITY,

WASHINGTON, D. C.

The 68th Annual Session will begin October 7th and end March 1st. Graded three years' course required. Women admitted. Professors: J. F. Thompson, W. W. Johnston, A. F. A. King, E. T. Fristoe, Wm. Lee, D. W. Prentiss, D. K. Shute.

For circulars, address
A. F. A. KING, M. D., DEAN, 726 THIRTEENTH ST., N. W., WASHINGTON D. C.

DETROIT COLLEGE OF MEDICINE.

SESSION 1889-90.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, Sept. 25, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins April 2d, 1890; and closes June 11th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

FACULTY:

JAMES R. LEAMING, M.D., Emeritus Professor of Diseases of the Chest and Physical Diagnosis; Special Consulting Physician in Chest Diseases to St. Luke's Hospital.

EDWARD B. BRONSON, M.D., Professor of Dermatology; Visiting Dermatologist to the Charity Hospital; Consulting Dermatologist to Bellevue Hospital (Out-door Department).

A. G. GERSTER, M.D., Professor of Surgery; Visiting Surgeon to the German and Mt. Sinai Hospitals.

V. P. GIBNEY, M.D., Professor of Orthopædic Surgery; Orthopædic Surgeon to the Nursery and Child's Hospital; Surgeon in-Chief to the Hospital for Ruptured and Crippled.

LANDON CARTER GRAY, M.D., Professor of Diseases of the Mind and Nervous System; Attending Physician to Hospital for Nervous and Mental Diseases, and to St. Mary's Hospital.

EMIL GRUENING, M.D., Professor of Ophthalmology; Visiting Ophthalmologist to Mt. Sinai Hospital, and to the German Hospital.

*JAMES B. HUNTER, M.D., Professor of Gynæcology; Surgeon to the Woman's Hospital; Surgeon to the New York Cancer Hospital; Consulting Surgeon to the New York Infirmary for Women and Children; President of the Faculty.

PAUL F. MUNDÉ, M.D., Professor of Gynæcology; Gynæcologist to Mt. Sinai Hospital; Consulting Gynæcologist to St. Elizabeth Hospital.

A. R. ROBINSON, M.D., Professor of Dermatology; Professor of Normal and Pathological Histology in the Woman's Medical College.

DAVID WEBSTER M.D., Professor of Ophthalmology; Surgeon to the Manhattan Eye and Ear Hospital.

JOHN A. WYETH, M.D., Professor of Surgery; Visiting Surgeon to Mt. Sinai Hospital; Consulting Surgeon to St. Elizabeth Hospital; Secretary of the Faculty.

W. GILL WYLIE, M.D., Professor of Gynæcology; Gynæcologist to Bellevue Hospital.

R. C. M. PAGE, M. D., Professor of General Medicine and Diseases of the Chest; Physician to St. Elizabeth Hospital; Attending Physician to the Northwestern Dispensary, Department of Chest Diseases.

D. BRYSON DELAVAN, M. D., Professor of Laryngology and Rhinology; Laryngologist to the Demilt Dispensary.

JOSEPH WILLIAM GLEITSMANN, M. D., Professor of Laryngology and Rhinology; Laryngologist and Octologist to the German Dispensary.

OREN D. POMEROY, M D., Professor of Otology; Surgeon Manhattan Eye and Ear Hospital; Ophthalmic Surgeon to New York Infants' Asylum, and Consulting Surgeon to the Paterson Eye and Ear Infirmary.

HENRY N. HEINEMAN, M. D., Professor of General Medicine and Diseases of the Chest; Attending Physician to Mt. Sinai Hospital.

B. SACHS, M.D., Professor of Diseases of the Mind and Nervous System; Consulting Neurologist to the Montefiore Home for Chronic Invalids.

THOMAS R. POOLEY, M.D., Professor of Ophthalmology; Surgeon-in-Chief of the New Amsterdam Eye and Ear Hospital; Ophthalmic Surgeon to the Sheltering Arms; Consulting Ophthalmologist to the St. Bartholomew's Hospital.

L. EMMETT HOLT, M.D., Professor of Diseases of Children; Visiting Physician to the New York Infant Asylum; Consulting Physician to the Hospital for Ruptured and Crippled.

AUGUST SEIBERT, M.D., Professor of Diseases of Children; Physician to the Children's Department of the German Dispensary.

H. MARION SIMS, M.D., Professor of Gynæcology, Gynæcologist to St. Elizabeth Hospital and New York Infant Asylum.

WILLIAM F. FLUHRER, M.D., Professor of Genito-Urinary Surgery; Surgeon to Bellevue and St. Sinai Hospitals.

HENRY C. COE, M. D., M. R. C. S. (Eng.), Professor of Gynecology; Attending Surgeon to New York Cancer Hospital; Assistant Surgeon to Woman's Hospital; Obstetric Surgeon to Maternity Hospital; Obstetrician to New York Infant Asylum; Gynecologist to Presbyterian Hospital, Out-door Department.

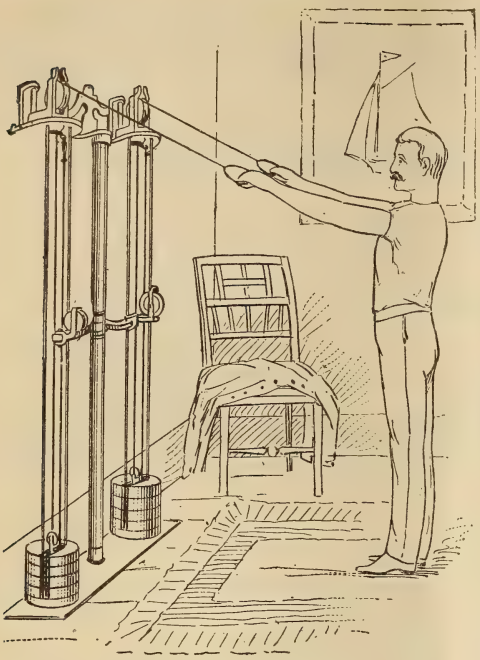
* Deceased.

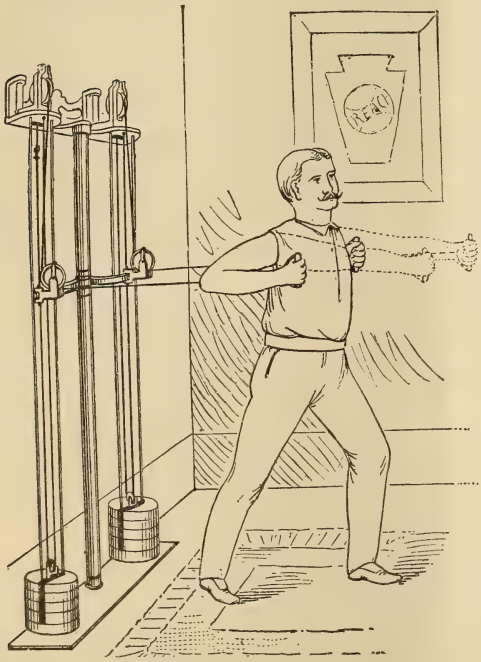
THE NEW YORK POLYCLINIC is a School of Clinical Medicine and Surgery for *Practitioners only*. No didactic lectures are given. The classes are limited. The demonstrations are made at the Polyclinic School and Hospital, and in the various Hospitals in New York City with which the Faculty are connected.

Session of 1889–90 opens Monday, September 16th, 1889. For further information and for catalogue, address

JOHN A. WYETH, M.D.,
Secretary of the Faculty,

Or WILLIS O. DAVIS, Clerk,
214, 216 & 218 East 34th Street, New York City.





A. G. SPALDING & BROS.'

Gymnasium Department.

It has become a matter of record, that hereafter the **Gymnasium** in all its details will be one of the leading features of our business.

With the addition to our own valuable patents, those of the **A. J. Reach Company,** of Philadelphia, recently purchased by us, enables us to claim the most **extensive department** of **Gymnasium Appliances in the world.**

We have been encouraged in this **important** movement by the constantly increasing demand from **Colleges, Seminaries,** and other **Educational** Institutions for Gymnasium Supplies, and henceforth we shall devote special attention to furnishing **plans, specifications,** and **estimates** to such and for **private residences** as well, and solicit correspondence with all contemplating the introduction of gymnastics for any purpose.

The Peerless Pulley Weight, illustration of which appears on this page, is a most perfect appliance for the development of the **chest** and **arms,** adjustable to the height of *any* person, and in weight from five to thirty pounds. For **man or woman** this is the peer of any method yet devised, especially for home use. Realizing the attention the **medical profession** and the **teacher,** are now giving to **healthful** exercise in **schools,** we solicit also their correspondence, and any orders, or business prceeding from such, will be gratefully received, and entitled to our best rates of discount, and will receive prompt and careful attention.

Visitors to our different establishments at **Chicago, New York,** and **Philadelphia** will always be welcome and politely served by the many efficient salesmen constantly in attendance.

A. G. SPALDING & BROS.,

CHICAGO, 108 Madison Street.
NEW YORK, 241 & 243 Broadway.
PHILADELPHIA, 1022 Market Street.
LONDON, ENGLAND, 38 Holborn Viaduct.

EXCERPTS.

PHENACETINE.—Dr. DUJARDIN-BEAUMETZ, Paris.—"It is above all as an analgesic that Phenacetine outrivals its predecessors. While it is quite as powerful as antipyrin and acetanilid, it does not cause the pain in the stomach, or the scarlatina-form rash of the former; nor does it give rise to the cyanosis of the latter. However prolonged may be its administration—and we have given it for months in doses of 1.0 to 2.0 Gm. (15 to 30 grains) per day—we have never observed any bad effect. We have used it for the relief of every form of pain (neuralgias, migraine, rheumatic pains, muscular rheumatism, acute articular rheumatism, the lightning pains of tabes, etc.) and always with the best results."

M. F. PRICE, M. D., President Southern California Medical Society.—"A patient says, 'I have headache,' and I order Phenacetine with confidence, and always with a report of relief."

THOS. W. AYERS, M. D., Jacksonville, Ala.—"As an antipyretic I have had nothing but the very best results from its use. As an antineuralgic there is no question, but it is superior to antipyrin. It is much more energetic in its action than either antipyrin or antifebrin."

SULFONAL.—HUNTER MCGUIRE, M. D., Richmond, Va.—"Has found it particularly valuable in insomnia following the use of alcohol."

HENRY M. WETHERILL, JR., M. D., Ph. G., Philadelphia.—"The almost universal report of Sulfonal is that it has little or no effect upon the vast majority of insomnous subjects save the important one of increasing, prolonging the natural tendency to sleep; that its action is not narcotic but purely hypnotic."

W. H. FLINT, M. D., New York (Discussion before N. Y. State Medical Association).—"He had used Sulfonal as being the most efficient or desirable of the new hypnotics. He had not yet seen a Sulfonal habit. There had been about eighty per cent. of successes in his cases."

JAMES STEWART, M. D., Montreal.—"Sulfonal produces no disagreeable secondary symptoms nor any unfavorable effects on the heart or circulation. Its action was by giving rest to the cells of the cerebral cortex and thereby causing sleep."

Sulfonal-Bayer has been before the Medical Profession for some time, receiving its unqualified endorsement, but the use has been limited in many cases, owing to the hesitation of the practicioner in recommending so costly a remedy.

A substantial reduction in price having been made, it enables physicians to freely prescribe it whenever indicated, and brings it within the reach of all classes of patients.

DR. WILLIAM A. HAMMOND'S SANITARIUM,

FOR DISEASES OF THE NERVOUS SYSTEM, Washington, D. C.

DR. WILLIAM A. HAMMOND announces to the medical profession that he has returned from New York to Washington, D. C., where he has established, in a building especially erected for the purpose, a *Sanitarium* for the treatment of mild and curable cases of mental derangement, diseases of the nervous system generally, cases of the morphia and chloral habits, and such other affections as may properly be treated by the remedial agencies under his control.

The *Sanitarium* is situated on Columbia Heights, at the corner of Fourteenth Street and Sheridan Avenue. The position is the highest in the immediate vicinity of Washington, the soil is dry, and all the surroundings are free from noxious influences. Electricity in all its forms, baths, douches, massage, inhalations, nursing, etc., are provided as may be required by patients, in addition to such other medical treatment as may be deemed advisable.

A large *Solarium* for sun-baths and exercise in cold or inclement weather and heated with steam in winter, is constructed on the top of the main building.

The *Sanitarium* has now been in successful operation since the 7th of January, 1889.

For further information Dr. Hammond can be addressed at The Sanitarium, Fourteenth Street and Sheridan Avenue, Washington, D. C.

Therapeutic Points.

Use McArthur's Syrup (Syrup Hypophos. Comp., C. P., McArthur) for Consumption, as it rapidly repairs the waste and restores vigor to the system.

For Tuberculosis in all forms, as it invigorates the tissue cells and enables them to overcome and expel the disease germs.

For Scrofula, as it builds up the tissue walls and thus breaks up the various inflammatory and suppurative processes incident to this diathesis.

For Inflammatory Diseases of the Throat, Bronchial Tubes, and Lungs, as its tonic and healing properties are nowhere better manifested than in this class of diseases.

For Rachitis, and all osseous degeneration, as it rapidly repairs bone tissue.

For Teething of Infants, as it furnishes food to the growing teeth. For the same reason you should give it to the nursing mothers and those whose teeth and bones are suffering during pregnancy.

For Chronic Diarrhœa, Leucorrhea, Suppurating Discharges and Sores.

For Chronic Alcoholism, the Morphine Habit, Brain Exhaustion, Loss of Memory, Neurasthenia, Spermatorrhea, Impotence, and all derangements of the nervous system. Here, by building up and restoring the nerve tissue, it effects a permanent cure, raising the patient from despondency to renewed hope and confidence, from weakness to strength and vigor.

For Uterine Fibroids and all forms of perverted nutrition, where it restores the normal processes of nutrition, and effects a recovery at once gratifying to the patient and satisfactory to the physician.

To obtain the best results, the Syrup should be given for a long time—weeks, months, and even years—until the disease is entirely eradicated and the patient no more susceptible to its return than if it "never had occurred."

As it is made only for Physicians' prescriptions, there are no labels, etc., on the bottle.

We will send our valuable treatise on "The Curability and Treatment of Consumption," free to any physician.

ANTIFEBRIN IN INFLUENZA!

This use of this Renowned ANTIPYRETIC, ANODYNE, SEDATIVE and NERVINE seems suggested by the following Judgments passed on it by Reputed Authorities in Symptomatically *Allied Complaints:*—

As an **Antifebrile** Dose:—2 to 4 grains *single;* 16 to 32 grains *daily.*—(WEINSTEIN, Vienna.)

As an **Anodyne** and **Nervine** Dose in severest Neurotic and Secondary Pains:—8 to 16 grains, *one to four times per day.*—(DEMIEVILLE, Lausanne.)

Mode of Administration:

"Even the *initial dose* gave evident relief; commonly within half an hour. If this did not suffice to break up the symptoms materially, a second dose followed in an hour or two; at the very utmost a third one was given the same day.

"The remedy was effective and well tolerated at all times; at all hours of the day; on an empty or a full stomach; even during menstruation.

"The form of exhibition was that of *powders*, wrapped in *wafers*. The readier solubility of the Antifebrin in Alcohol indicates the advisability of following the dose by a small draught of Wine or Brandy."—(OTT, Prague.)

ANOTHER MODE OF ADMINISTRATION:—*Dissolve* your Dose (4 to 12 grains) of **ANTIFEBRIN** in ½–1 ounce (1 to 2 Tablespoonfuls) of *Boiling Water*,—stirring for a minute or two, until dissolved. Allow the Solution *to cool down* to about 104 degrees F. (being just comfortably warm) and sweeten to taste, *Before Taking!*—NO ALCOHOL, WINE, or LIQUOR needed with it when thus prepared.

ANTIFEBRIN

was found **Superior** to the **Following** Remedies in **Efficacy**, or in **Safety**, or in **Both**:—

Antipyrine,—*Quinine*,—*Morphine*,—*Opium*,—CHLORAL HYDRATE—ACONITE,—CAFFEINE,—KAIRINE,—*Salicylic Acid*,—CARBOLIC ACID,—*Bromides*,—IODIDES.

Among the Medical Authorities from whose Clinical and other Published Reports the above-stated PREFERENCES OF ANTIFEBRIN OVER OTHER REMEDIES have been drawn, are the following:

HARE, University of Pennsylvania;—DUJARDIN-BEAUMETZ, Paris;—HERCZEL, Heidelberg;—MURRAY, *Brit. Med. Journal:*—PAVAIVAJNA, *Centralblatt für die gesammte Therapie;*—BARR, Bridgeport, Ill.;—KELL, Delphos, O.;—HAY, New York;—HAAS, Prague.

Antifebrin was also *found to be:*

"Thoroughly *reliable* as an ANTIPYRETIC."—(DEMME, Berne.)

"*Not only* powerfully ANTITHERMIC, but also a most *useful* NERVINE."—(LEPINE, Lyons.)

"A *powerful, safe*, and *certain* ANTITHERMIC agent."—(EVANS, Easton, Pa.)

"*Complete* ANALGETIC effect in nine cases out of every ten."—(FISCHER, Cannstatt.)

PHENACETINE-BAYER IN INFLUENZA.

We have just received advices that Phenacetine-Bayer is being used to advantage both in Russia and Germany, in the treatment of the present epidemic of **INFLUENZA.** It is also being extensively employed in America for the same purpose.

Dr. A. C. HALLAM, Brooklyn, N. Y., states :—"That he has used Phenacetine extensively in the present epidemic of Influenza and has been well pleased with its effects. The rapidity with which it relieves the muscular pains has been very gratifying to him, the patient breaking out in a profuse perspiration, and in a few hours seeming relieved of all but the catarrhal symptoms, which run on and call for other treatment."—*The New York Medical Journal,* Jan. 4, 1890.

221 GENESEE STREET, UTICA, N. Y., January 6, 1890.

To the Editor of the New York Medical Journal:

SIR: I desire to echo the statement made in your last issue by Dr. A. C. Hallam, of Brooklyn, viz.: That in the treatment of fifty cases of influenza I have used phenacetine in five-grain doses repeated hourly until fifteen grains had been taken, and in *every case* the severe muscular pains and headache disappeared; following this with five-grain doses, three times daily, of the salicylate of cinchonidine. The disease disappeared upon the fourth day, and in *no cases* have there been any sequelæ either of bronchitis or pneumonia. Phenacetine, I consider superior in every way to antipyrine and acetanilide.

CHARLES R. WEED, M. D.

Phenacetine-Bayer (Para-Acetphenetidine), prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, is supplied by us in one-ounce vials and also in the form of our soluble pills, containing two, four, and five grains each. Either form may be obtained of any reputable apothecary.

W. H. Schieffelin & Co.,

NEW YORK.

A Peerless Chemico-Physiological Food and Restorative

Crystalline Phosphate

A TISSUE FOOD

PHOSPHATIC GOOD PRODUCTS TRADE MARK

Contains all essential inorganic components of the tissues in a semi-solid, easily soluble, crystalline mass,

COMPOSED OF

ACID PHOSPHATE OF CALCIUM.

WITH

Acid Phosphate of Magnesium,
" " " Iron,
" " " Sodium,
" " " Potassium,
Chloride of Potassium,
" " Sodium
Sulphate of Potassium,
and Phosphoric acid.

INDICATIONS:

STOMACH DISORDERS, such as Indigestion, Flatulence Gastric Catarrh, and Poor Appetite, Constipation, etc.

WRONGS OF NUTRITION, as in Scrofula, Rickets, Caries, Marasmus, Delayed Union of Fractures, Necrosis of Tissue, Difficult or Delayed Dentition and Development, etc.

NERVOUS AND GENERAL DEBILITY AND SLEEPLESSNESS, as from Sexual Excess, Venerial Disease, Childbearing, Nursing, Loss of Blood or other fluids, Menstrual and other Diseases of Women, abuse of Alcohol, Tobacco and Narcotics, Protracted Illness, etc.

PROF. KONN B. SAYRES, M. D., Demonstrator of Anatomy, Miami Medical College, Cincinnati, O.

I am pleased to inform you that I have during about six months last past made a critical trial of your Crystalline Phosphate, in various cases of mal-nutrition, nervous prostration, atonic dyspepsia, insomnia and kindred derangements of the vital functions, which has demonstrated the fact that it is a preparation of *very great value.* I believe your representations concerning it are fully justified by actual and palpable results in my practice, and I very cheerfully recommend it, knowing that a fair trial will prove it worthy of the confidence of the profession.

Write for Samples and Treatise—Mailed Free. Mention this Journal.

PROVIDENT CHEMICAL WORKS, - - ST. LOUIS, MO., U. S. A.

E. C. RICH CO., Limited, New York City, Eastern Agents,

A Phosphorized Cerebro-Spinant

(FRELIGH'S TONIC).

FORMULA.

Ten minims of the Tonic contain the equivalents (according to the formulæ of the U. S. P., and Dispensatory) of

Tinct. Nux Strychnos,	1 minim.
" Ignatia Amara,	1 "
" Cinchona,	4 "
" Matricaria,	1 "
" Gentian,	½ "
" Columbo,	½ "
" Phosphorus, C. P.,	1-300 gr.
Aromatics,	2 minims.

Dose: 5 to 10 drops in 2 tablespoonfuls of water.

INDICATIONS.

Paralysis, Neurasthenia, Sick and Nervous Headache, Dyspepsia, Epilepsy, Locomotor Ataxia, Insomnia, Debility of Old Age, and in the Treatment of Mental and Nervous Diseases.

A BALTIMORE PHYSICIAN, WHOSE DIPLOMA DATES FROM 1825, SAYS:

"Your combination I find vastly more effective than any tonic I have ever used. It furnishes a most powerful evidence of the vastly increased power of medicament by combination and judicious pharmaceutic preparation."

Price, One Dollar per Bottle, containing 100 of the Average 5-Drop Doses.—Physicians' single sample delivered, charges prepaid, on application. That every physician may be his own judge of its value, irrespective of the opinions of others, we make the following

SPECIAL OFFER:

We will send to any physician, delivered, charges prepaid, on receipt of twenty-five cents, and his card or letter-head, half a dozen physicians' samples, sufficient to test it on as many cases for a week to ten days each. The Tonic is kept in stock regularly by all the leading wholesale druggists of the country. As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-lists, etc., address,

Manufacturers of Physicians' Specialties,

No. 88 Maiden Lane, New York City.

LENTZ'S ASEPTIC COMPACT OPERATING SET, No. 10.

We have from time to time made improvements to this set and are now making a perfect aseptic set, which offers especial facilities for aseptic precautions; the blades are soldered into hollow German-silver handles, nickel-plated, are light so as not to be unwieldy and admit of a firm grasp when operating.

The saw is adjusted to the handle on an entirely new principle, being made to separate easily and to facilitate thorough cleansing.

The handle is entirely of metal and fenestrated to overcome unnecessary weight.

Scissors and Forceps having French locks can be separated, and the slide can be easily removed from Artery and Needle Forceps.

Therefore, no opportunity is offered for the lodgment and development of germs.

The entire set is patterned with especial reference to facility in cleansing.

The instruments can be sterilized by placing them in boiling water, without fear of damaging them. Wood or rubber handles will not admit of this procedure. For price, see case A.

The following instruments are put up in either a fine Mahogany or Morocco case, with nickel trimmings, lined with velvet, and has an extra space for Trephine with handle, and Elevator if desired.

One Amputating Knife (6 in. blade); One Finger Knife; One Hernia Knife; One Sharp Curved Bistoury; Two Scalpels; One Tenotome; One Tenaculum; One Pair Scissors, curved or flat; One Saw (9 in. blade); One Liston's Bone Forceps, with Spring; One Artery and Needle Forceps, improved; One Esmarch's Flat Rubber Tourniquet, with Chain; One Hæmostatic Forceps; One Director, with Aneurism Needle; Two Silver Probes; Silk, Wire, Wax and Needles.

With the Sixteen Instruments Contained in this Case, any Ordinary Operation may be Performed.

SIZE, 11 INCHES LONG, 4 INCHES WIDE, 2 INCHES HIGH.

A.—German Silver aseptic Handles on Knives and Saw, ... $34 00
B.—Hard Rubber aseptic Handles on Knives and Saw, ... 29 00
C.—Ebony Handles on Knives and Saw (as shown in illustration), ... 25 00
Either Set, with Trephine and Elevator in addition, ... 4 65

DISCCUNT 25 PER CENT. TO PHYSICIANS. Our Catalogue of 260 pages will be sent on receipt of 10 cts. for postage.

CHARLES LENTZ & SONS, Manufacturers of Surgical and Orthopædic Apparatus,

Established 1866. **18 North Eleventh Street, Philadelphia.**

The Acutely Ill.

When a patient is acutely ill, the digestive powers share in the general condition, and consequently the food supplied should be of the most easily assimilable character. The predigestion of starchy matters outside the body, as in MELLIN'S FOOD, is necessary, and the soluble carbohydrates of which this food consists, soluble because predigested, form the true food of the acutely ill.—J. MILNER FOTHERGILL, M.D., Edin.

A sample of MELLIN'S FOOD *will be sent to any physician, free of expense, upon application.*

Doliber-Goodale Co., Boston, Mass.

BINDER FOR THE "Reporter,"

Price, 50 cents.

To persons who are seeking a Perfectly Safe and Desirable Investment,

I can unhesitatingly recommend, and back by my name and reputation, **a Bond paying 6 per cent. interest clear of State tax,** secured by a paid-up capital of $500,000 and collateral deposited with the Girard Life Insurance, Annuity and Trust Company of Philadelphia, as Trustee for the bondholders. Principal and interest payable at the office of "The Girard," where Bonds can be registered if desired. Price of Bonds par and accrued interest. For full detailed information, apply to

WM. P. HUSTON,

Nine years Actuary of the Girard Life Insurance, Annuity and Trust Company, at office in "GIRARD BUILDING."

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

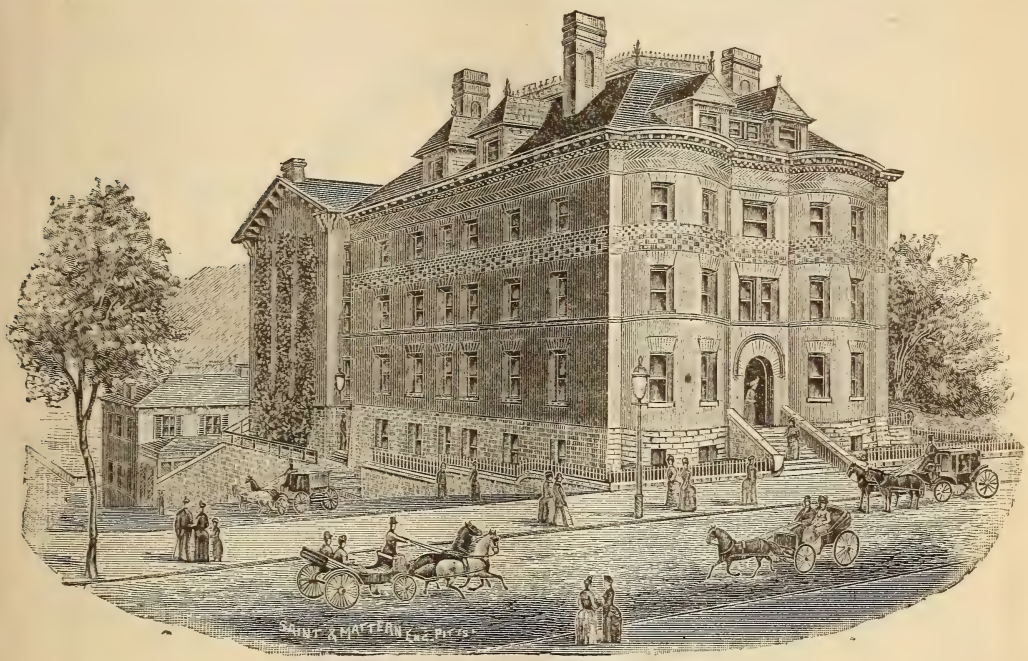
DR. R. S. SUTTON'S

Sanatorium for Diseases of Women.



Seventh Year Opens September 1, 1889.

ALLEGHENY CITY, PA.

This Institution is located on high ground, and overlooks the Allegheny, Monongahela and Ohio rivers; it commands a view of the city of Pittsburgh, and its picturesque surroundings. The building is large and beautiful, it is provided with every modern convenience, the halls are heated by steam, the rooms are commodious, well lighted and ventilated, and heated by open grates. The house is provided with a private parlor and reading-room for patients. The dining-room is large, handsomely finished, and furnished with small tables, securing privacy at meals for those who do not care to have meals served in their own rooms. Patients can be as secluded, should they desire it, as in a well appointed hotel. Each patient is examined by Dr. Sutton, and receives his daily personal attention, while Dr. J. H. Williamson, a physician of ample hospital experience, resides in the Institution, and has, under Dr. Sutton, the immediate care of the patients. The Institution accommodates 25 patients, and is equal in comfort to the best hotels.

Electricity, baths, douches, massage, local treatment, general medication and surgical operations are resorted to according to the requirements of each patient.

For further information address the Matron

MISS KENNEDY,

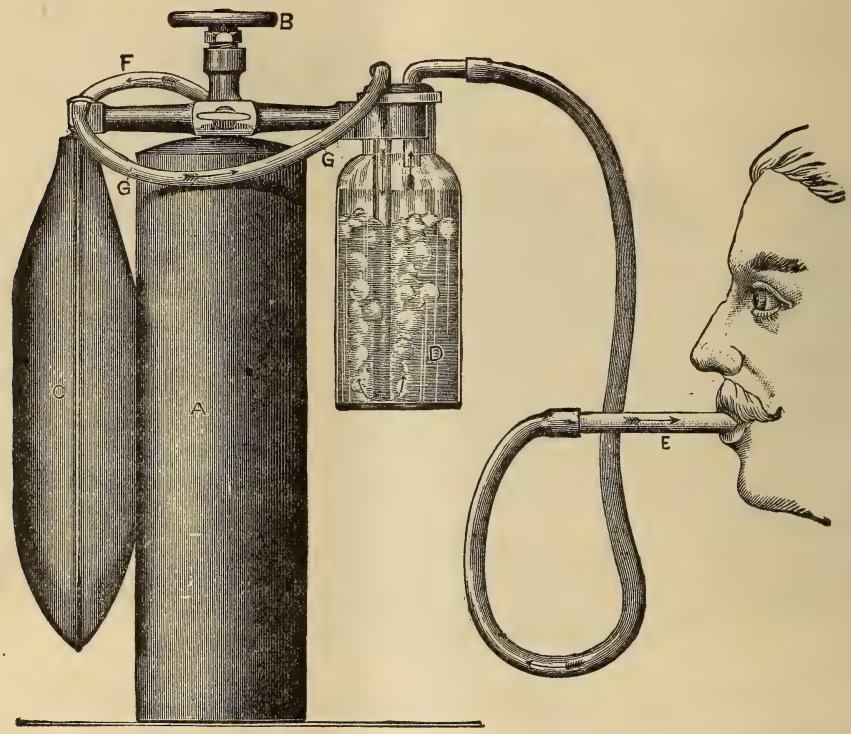
INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed O. ·en and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.
LAMBERT'S
LITHIATED HYDRANGEA
KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request.

Geo Hamlin Prest. Chas Roome Parmele Treas.

GENTLEMEN:

The Case of your wines sent me for analysis by Dr. A. L. Hummel, of the "Annals of Hygiene," containing specimens of your La Rosa Zinfandel, Mataro, Riesling, Royal Tokay, and Royal Grape Brandy, has been duly received.

I have examined them for the common contaminants of wine; to wit: Sulphurous acid and sulphites, salicylic acid, fuchsin, lead salts, etc., none of which I found present therein.

I have also determined their alcoholic strength, extractives, and ashes, and found them to correspond strictly in this respect with the standard of pure and natural wines, which cannot be said of many of the imported wines.

As a native of a wine-producing country, I consider myself somewhat of a judge of wines, and regard your products as comparing more than favorably with most of the wines from abroad which are sold at higher prices, so much so that I enclose within my order for fifty bottles of La Rosa Zinfandel, which I expect to use hereafter exclusively at my table.

Very Respectfully,

L. WOLFF, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

Champagne ANALYZED

Of Interest to all Medical Practitioners.

WHAT IS SAID BY

THOMAS KING CHAMBERS, M.D., F.R.C.P.
R. OGDEN DOREMUS, M.D.
F. W. PAVY, M.D., F.R.S.

"Champagne, with a minimum of alcohol, is by far the wholesomest, and possesses remarkable exhilarating power."—THOMAS KING CHAMBERS, M.D., F.R.C.P.

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most prominent brands of Champagne. I find G. H. Mumm & Co.'s Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it not only for its purity but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M.D., *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

"Champagne, while only possessing the alcoholic strength of natural wines, is useful for exciting the flagging powers in case of exhaustion"—F. W. PAVY, M.D., F.R.S., *Lecturer on Physiology at Guy's Hospital, London.*

The remarkable vintage of 1884 of **C. H. MUMM & CO.'S EXTRA DRY CHAMPAGNE,** the finest for a number of years, is now imported into this market, and pronounced by connoisseurs unsurpassed for excellence and bouquet.

FRED'K DE BARY & CO., New York,

SOLE AGENTS IN THE UNITED STATES AND CANADA.

Permanent Pepsin.

THE INSEPARABLE STANDARDS OF VALUE ARE PERMANENCY AND ACTIVITY.

WHEN a physician prescribes pepsin and his patient finds that it "sticks to the paper," that it forms a gummy mass "in powders," he may rely upon it that FAIRCHILD'S PEPSIN has not been dispensed; if he has ordered Fairchild's, this behavior is positive evidence that he and his patient have been the victims of "substitution."

Pepsins which are hygroscopic, which do undergo upon exposure to air the changes characteristic of peptone, are offered (in the form of scales and in powder) with pretensions to permanent quality.

If a product is sought, of well-proven permanency and of highest standard of activity, FAIRCHILD'S PEPSIN is the one which will never give cause for complaint.

Fairchild's was the original "Scale Pepsin;" the first positively "free from starch, sugar, acid, peptones or any added substance." The host of imitations of "Scale Pepsin" bear witness to the value and reputation of the original.

FAIRCHILD BROS. & FOSTER,

82 and 84 Fulton Street, New York.

Apollinaris

"THE QUEEN OF TABLE WATERS."

The filling at the Apollinaris Spring (Rhenish Prussia), amounted to

11,894,000 BOTTLES IN **1887,**
12,720,000 BOTTLES IN **1888** AND
15,822,000 BOTTLES IN **1889.**

"The annual consumption of this favorite beverage affords a striking proof of the widespread demand which exists for table water of absolute purity, and it is satisfactory to find that, wherever one travels, in either hemisphere, it is to be met with; it is ubiquitous, and should be known as the cosmopolitan table water. 'Quod ab omnibus, quod ubique.'"—BRITISH MEDICAL JOURNAL.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word **"Hunyadi"** forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

THE VALUE OF NUTRITION IN DISEASE.

All physicians who have ever used Murdock's Liquid Food and Suppositories recognize their value over all other foods, in breaking up disease and building up the patients after disease, preventing a relapse, **as the same results are obtained as in surgery.** Its value in surgical cases we illustrate by the records of the different cities and of Murdock's Free Surgical Hospital for Women, which is the largest in the United States. It contains 114 beds, every bed free, including operation, the operations ranging from 1000 to 1200 yearly, representing 90 of the worst classes known in surgery. Among these cases we have had **Cancer of uterus** (*Kolpo-hysterectomy*), 13; **Salpingitis** (*Tait's operation*), 31; **Fibroid of uterus** (*abdominal hysterectomy*), 19; **Ventral operation, hernia,** (*abdominal section*), 12; **Cancer of bowel** (*incision*), 2; **Parovarian cyst, 6; Papillomatous cyst** (*extirpation*), 4; **Tubercular peritonitis** (*incision*), 1, **Ovarian cystoma 27; Nymphomania** (*Battey*), 1; **Exploratory abdominal incisions, 12; Fibroid with abdominal abscess** (*Hegar*), 2; **Hysterorraphy, 2; Dermoid cyst, 3; Cirrhotic ovaries,** (*Battey*), 4; **Fibroid uterus** (*Hegar*), 6; **Hystero-epilepsy** (*Battey*), 1; **Haemato-Salpinx** (*Tait*), 5; **Rupture of intestine into vagina, 1; Dislocated kidney, 2; Fibroid tumor abdominal wall, 1; Resection of intestine** (*Senn*), 1; **Ruptured perineum, 294.** Patients are in the Hospital 8 days before and 26 days after operation, on an average.

In Boston, last year, 42 deaths were from Cancer in the Breast. In Murdock's Hospital, 35 such cases were operated on without a death, the patients remaining in the Hospital, on an average, 18 days.

Mortality	in Boston,	25.60	per 1000.
"	of Women in Boston,	29,00	" "
"	**in Murdock's Free Surgical Hospital,**	**5.00**	" "
"	New York,	26.32	" "
"	Philadelphia,	20.00	" "
"	Chicago,	20.90	" "
"	St. Louis,	20.49	" "

showing our mortality is only one-sixth as great as of those in health. As good results were obtained in our General Hospital, which we kept open 27 months, **thus showing the value of nutrition as found in Murdock's Liquid Food, and so recognized by the British and American Medical Associations,** before which essays were read and discussed, and it is the only Raw food preparation on which essays were ever read.

Physicians are invited to visit our Hospitals and Works, also to send in patients and to be present at the operations. For any physician who has not used our Liquid Food (and Suppositories for adults and infants), we will deliver free samples to any express company in Boston.

When babies do not thrive, never change their food, but add five or more drops at each feeding of Murdock's Liquid Food, and their lost or needed vitality will be restored in less than thirty days. It is invaluable when weaning babies or when teething. If mothers will take one teaspoonful to a tablespoonful before each meal and on retiring, they will receive as much benefit as the baby.

Murdock Liquid Food Co., Boston.

GARDNER'S

SYRUP OF HYDRIODIC ACID,

Introduced in 1878 by R. W. GARDNER.

The Reputation which Hydriodic Acid has Attained During the past Eleven Years was Won by this Preparation.

Numerous Imitations prepared differently, and weaker in Iodine, are offered, from the use of which the same therapeutic effects cannot be obtained.

Caution.—Use no Syrup of Hydriodic Acid which has turned red. This shows decomposition and free Iodine. In this state it acts as an irritant and fails to produce desirable results.

Unprincipled apothecaries substitute imitations when Gardner's Syrup is prescribed, and physicians, failing to get desirable and promised results, attribute the fault, unjustly, to Gardner's Syrup.

THERAPEUTIC INDICATIONS.

Hay Fever; Rose Cold; Poisoning by Lead, Mercury or Arsenic; Acute and Chronic Rheumatism; Asthma; Chronic Bronchitis; Catarrh; Congestion of Lungs in Children; Adenitis; Eczema; Lupus; Chronic Malarial Poisoning; Lumbago; Acute Pneumonia; Psoriasis; Scrofulous Diseases; Goitre; Enlarged Glands; Cold Abscesses; Indolent Sores; Excessive Fat; Fatty Degeneration of the Heart; to absorb non-malignant Tumors; and in the latter stages of Syphilis; Syphilitic Phthisis.

Details of treatment furnished physicians upon application to undersigned without charge.

Gardner's Chemically Pure Syrups of Hypophosphites.

Embracing the separate Syrups of Lime, of Soda, of Iron, of Potassa, of Manganese, and an Elixir of the Quinia Salt; enabling physicians to accurately follow Dr. Churchill's method, by which thousands of authenticated cases of Phthisis have been cured. The only salts, however, used by Churchill in Phthisis are those of Lime, of Soda, and of Quinia, and always separately according to indications,—never combined.

The reason for the use of single Salts is because of antagonistic action of the different bases, injurious and pathological action of Iron, Potassa, Manganese, etc., in this disease.

These facts have been demonstrated by thirty years' clinical experience in the treatment of this disease exclusively, by Dr. Churchill, who was the first to apply these remedies in Medical practice. Modified doses are also required in this disease; seven grains during twenty-four hours being the maximum dose in cases of Phthisis, because of increased susceptibility of the patient to their action, the danger of producing toxic symptoms (as hemorrhage, rapid softening of tubercular deposit, etc.), and the necessity that time be allowed the various functions to recuperate simultaneously; over-stimulation, by pushing the remedy, resulting in crisis and disaster.

A pamphlet of sixty-four pages, devoted to a full explanation of these details and others, such as contra-indicated remedies, indications for the use of each hypophosphite, reasons for the use of absolutely pure Salts, protected in Syrup from oxidation, etc., mailed to physicians without charge upon application to

R. W. GARDNER, 158 William St., N. Y. City.

W. H. SCHIEFFELIN & CO., Sole Wholesale Agents, New York.

Nerve-Counterfeits of Uterine Disease.

Dr. Wm. Goodell, the well-known Professor of Gynecology, Univ. Penn., Philadelphia, says:

"*The symptoms of nerve-prostration so greatly resemble those of even coarse uterine lesions* that the nerve-mimicries can very readily be mistaken for signals of actual organic disease. Nor, indeed, are they always distinguishable the one from the other, for the marvelous kinship between mind and matter is a tangled skein, not yet unraveled by dead-house or by laboratory.

"What, then, are these symptoms? Their name is legion, but the most common ones are, strangely enough, those which lay and professional tradition, with singular consent, have labeled as the symptoms *par excellence* of womb disease. They are, in the order of their frequency, great weariness, more or less of nervousness and of wakefulness; inability to walk any distance, and a bearing-down feeling; headache, nape-ache, and backache; cold feet, an irritable bladder, spinal tenderness, and pain in one ovary, usually the left, or in both ovaries. The sense of exhaustion is a remarkable one; the woman is always tired; she passes the day tired, she goes to bed tired, and she wakes up tired, often, indeed, more tired than when she fell asleep. She sighs a great deal, and her arms and legs tremble or 'fall asleep' so frequently that she fears palsy or paralysis.

"Other symptoms, not quite so common, are the cerebral ones, such as low spirits, bad dreams, nightmares, and night-terrors; explosive sounds in the head, a loss of memory, suicidal thoughts, the fear of impending insanity, the dread of being left alone, or of being in a crowd.

"From a large experience I humbly offer to the reader the following watchwords as broad helps to diagnosis:

"*First.* Always bear in mind what another has pithily said, that 'woman has some organs outside of the pelvis.'

"*Secondly.* Each neurotic case will usually have a tale of fret or grief, of cark and care, of wear and tear.

"*Thirdly.* Scant or delayed or suppressed menstruation is far more frequently the result of nerve-exhaustion than of uterine disease.

"*Fourthly.* Anteflexion *per se* is not a pathological condition. It is so when associated with sterility or with painful menstruation, and only then does it need treatment.

"*Fifthly.* An irritable bladder is more often a nerve symptom than a uterine one.

"*Sixthly.* In a large number of cases of supposed or of actual uterine disease which display marked gastric disturbance, if the tongue be clean, the essential disease will be found to be neurotic; and it must be treated so.

"*Seventhly.* Almost every supposed uterine case, characterized by excess of sensibility and by scantiness of will-power, is essentially a neurosis.

"*Eighthly.* In the vast majority of cases in which the woman takes to her bed and stays there indefinitely, from some supposed uterine lesion, she is bed-ridden from her brain and not from her womb. I will go further, and assert that this will be the rule even when the womb itself is displaced, or it is discovered by a disease or by a lesion that is not in itself exacting or dangerous to life.

"*Finally.* Uterine symptoms are not *always* present in cases of uterine disease. Nor when present, and even urgent, do they *necessarily* come from uterine disease, for they may be merely nerve-counterfeits of uterine disease."

The best remedial agent for the above nerve troubles, so well described by Prof. Goodell, is that well-known remedy, CELERINA (Rio), in teaspoonful doses thrice daily. Where uterine disease is also suspected, the best prescription, as largely attested by the profession, is

℞ Celerina (Rio), ... 4 ounces.
Aletris Cordial (Rio), . . . 4 ounces.
M. Sig.: Teaspoonful four times a day.

ESTABLISHED 1855.

DRS. STRONG'S SANITARIUM,

SARATOGA SPRINGS, NEW YORK,

Receives persons recommended to it by their home physicians for Treatment, Change, Rest or Recreation, and places them under well-regulated hygienic conditions so helpful in the treatment of chronic invalids or the overtaxed.

For Treatment: In addition to the ordinary remedial agents, it employs Turkish, Russian, Roman, Sulphur, Electro-Thermal, the French Douche (Charcot's), and all Hydropathic Baths; Vacuum Treatment, Swedish Movements Massage, Pneumatic Cabinet, Inhalations of Medicated Compressed, and Rarefied Air, Electricity in various forms, Thermo-Cautery, Calisthenics, and Saratoga Waters, under the direction of a staff of educated physicians.

For Change: This Institution is located in a phenomenally dry, tonic, and quiet atmosphere, in the lower arc of the Adirondack Zone, and within the "Snow Belt."

For Rest: The Institution offers a well-regulated, quiet home, heated by steam and thoroughly ventilated, with cheering influences and avoiding the depressing atmosphere of invalidism.

For Recreation: To prevent introspection, are household sports at all seasons of the year, and in Winter, tobogganning, elegant sleighing, etc.; in Summer, croquet, lawn-tennis, etc.

Private professional references furnished upon application. Physicians are invited to inspect the Institution at their convenience. A liberal discount to physicians and their families.

For further information, address,

DRS. S. S. & S. E. STRONG.

THE OLD STYLE discarded on account of pulling apart, while the elastic is still in good condition.

THE "MASTER" SURGICAL ELASTIC STOCKINGS

FOR VARICOSE VEINS, WEAK AND SWOLLEN JOINTS, DROPSY OF THE LIMBS, SPRAINS, etc.

PROVIDED WITH

THE PATENT NON-ELASTIC STAYS AND ADJUSTING LOOPS,

By the aid of which they can be drawn on easily, like pulling on a boot. They will last much longer than the old style, as the stays prevent them from being torn apart in drawing them on.

ALL KINDS AND SIZES IN THREAD OR SILK ELASTIC. Made under D. Master's Patents, Nov. 29, 1881, March 21, 1882. Send for descriptive circular and price-list to

POMEROY TRUSS CO.,

785 Broadway, New York.

DANIEL POMEROY, Pres. CHARLES R. DEAN, Sec.

THE NEW STYLE cannot pull apart and consequently lasts until worn out.

ONEITA

The perfection of table waters, with mineral properties unsurpassed in the treatment of Dyspepsia, Kidney and Liver troubles, Gout, Rheumatism, etc. The analysis of the spring shows a combination of mineral virtues unequaled in any other water. The water has been before the public but a short time, yet in that time has won public favor to a marked degree. Send for analysis of C. F. Chandler, Ph. D.

ONEITA SPRING CO.,

UTICA, N. Y.

ANTISEPTIC DRAINAGE TUBES.—Glass.

These Tubes have large holes, one-half inch apart, arranged alternately on opposite sides.

They are carefully finished, especial care being taken to make them smooth.

In addition to the drainage-holes, each tube has at one end two smaller holes for the insertion of Safety-Pin, through which it is prevented slipping into the wound.

FURNISHED IN SEVEN SIZES.

No. 1,	$1.25 per doz.	No. 4,	$1 55 per doz.
No. 2,	1.25 "	No. 5,	1.70 "
No. 3,	1.40 "	No. 6,	1.90 "

No. 7, $2.10 per dozen.

RAW CAT-GUT. I put this up in coils of 10 feet, four difierent sizes, Nos. 1, 2, 3, 4 (4 is thickest). Nos. 2 and 3 are the most useful sizes. **No. 1 Coil, 10 Cents; No. 2 Coil, 12 Cents; No. 3 Coil, 14 Cents; No. 4 Coil, 16 Cents.** Full directions with each coil for making it absolutely aseptic.

WILLIAM SNOWDEN,

Manufacturer, Importer and Exporter of Surgical Instruments,

No. 7 SOUTH ELEVENTH STREET, PHILADELPHIA.

UNIVERSITY OF PENNSYLVANIA.—Medical Department.

The 124TH ANNUAL WINTER SESSION began Tuesday, October 1st, 1889, at 12 M., and will continue until May 1st, 1890.
The PRELIMINARY SESSION began September 18th, 1889.
The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology, with Bedside Instruction in Medicine, Surgery and Gynecology are a part of the regular course and without additional expense.

FACULTY.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
D. HAYES AGNEW, M.D., LL.D., Honorary Professor of Clinical Surgery.
WILLIAM PEPPER, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
WILLIAM GOODELL, M.D., Professor of Gynecology.
JAMES TYSON, M.D., Professor of Clinical Medicine.
HORATIO C. WOOD, M.D., LL.D., Professor of Materia Medica, Pharmacy and General Therapeutics.
THEODORE G. WORMLEY, M.D., LL.D., Professor of Chemistry and Toxicology.
JOHN ASHHURST, JR., M.D., Professor of Surgery and of Clinical Surgery.
EDWARD T. REICHERT, M.D., Professor of Physiology.
WILLIAM F. NORRIS, M.D., Honorary Prof. of Ophthalmology
BARTON COOKE HIRST, M.D., Professor of Obstetrics.
J. WILLIAM WHITE, M.D., Professor of Clinical Surgery.
JOHN GUITÉRAS, M.D., Professor of General Pathology and Morbid Anatomy.
GEORGE A. PIERSOL, M.D., Professor of Histology and Embryology.
SAMUEL G. DIXON, M.D., Professor of Hygiene.

For Catalogue and announcement containing particulars, apply to

Address,

MEDICAL AND SURGICAL REPORTER,

P. O. Box 843. PHILADELPHIA.

WESTERN PENNSYLVANIA MEDICAL COLLEGE
CITY OF PITTSBURGH.

SESSIONS OF 1889—90.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. J. W. J. MCKENNAN.

Business correspondence should be addressed to
PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

NATIONAL MEDICAL COLLEGE.
MEDICAL DEPARTMENT OF THE
COLUMBIAN UNIVERSITY,
WASHINGTON, D. C.

The 68th Annual Session will begin October 7th and end March 1st. Graded three years' course required. Women admitted. Professors: J. F. Thompson, W. W. Johnston, A. F. A. King, E. T. Fristoe, Wm. Lee, D. W. Prentiss, D. K. Shute.

For circulars, address
A. F. A. KING, M. D., DEAN, 726 THIRTEENTH ST., N. W., WASHINGTON D. C.

DETROIT COLLEGE OF MEDICINE.
SESSION 889-90.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, Sept. 25, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins April 2d, 1890; and closes June 11th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to
H. O. WALKER, M.D., Secretary,
33 Lafayette Ave., Detroit, Mich.

FACULTY:

JAMES R. LEAMING, M.D., Emeritus Professor of Diseases of the Chest and Physical Diagnosis; Special Consulting Physician in Chest Diseases to St. Luke's Hospital.

EDWARD B. BRONSON, M.D., Professor of Dermatology; Visiting Dermatologist to the Charity Hospital; Consulting Dermatologist to Bellevue Hospital (Out-door Department).

A. G. GERSTER, M.D., Professor of Surgery; Visiting Surgeon to the German and Mt. Sinai Hospitals.

V. P. GIBNEY, M.D., Professor of Orthopædic Surgery; Orthopædic Surgeon to the Nursery and Child's Hospital; Surgeon-in-Chief to the Hospital for Ruptured and Crippled.

LANDON CARTER GRAY, M.D., Professor of Diseases of the Mind and Nervous System; Attending Physician to Hospital for Nervous and Mental Diseases, and to St. Mary's Hospital.

EMIL GRUENING, M.D., Professor of Ophthalmology; Visiting Ophthalmologist to Mt. Sinai Hospital, and to the German Hospital.

*JAMES B. HUNTER, M.D, Professor of Gynæcology; Surgeon to the Woman's Hospital; Surgeon to the New York Cancer Hospital; Consulting Surgeon to the New York Infirmary for Women and Children; President of the Faculty.

PAUL F. MUNDÉ, M.D., Professor of Gynæcology; Gynæcologist to Mt. Sinai Hospital; Consulting Gynæcologist to St. Elizabeth Hospital.

A. R. ROBINSON, M.D., Professor of Dermatology; Professor of Normal and Pathological Histology in the Woman's Medical College.

DAVID WEBSTER M.D., Professor of Ophthalmology; Surgeon to the Manhattan Eye and Ear Hospital.

JOHN A. WYETH, M.D., Professor of Surgery; Visiting Surgeon to Mt. Sinai Hospital; Consulting Surgeon to St. Elizabeth Hospital; Secretary of the Faculty.

W. GILL WYLIE, M.D., Professor of Gynæcology; Gynæcologist to Bellevue Hospital.

R. C. M. PAGE, M. D., Professor of General Medicine and Diseases of the Chest; Physician to St. Elizabeth Hospital; Attending Physician to the Northwestern Dispensary, Department of Chest Diseases.

D. BRYSON DELAVAN, M. D., Professor of Laryngology and Rhinology; Laryngologist to the Demilt Dispensary.

JOSEPH WILLIAM GLEITSMANN, M. D., Professor of Laryngology and Rhinology; Laryngologist and Octologist to the German Dispensary.

OREN D. POMEROY, M.D., Professor of Otology; Surgeon Manhattan Eye and Ear Hospital; Ophthalmic Surgeon to New York Infants' Asylum, and Consulting Surgeon to the Paterson Eye and Ear Infirmary.

HENRY N. HEINEMAN, M. D., Professor of General Medicine and Diseases of the Chest; Attending Physician to Mt. Sinai Hospital

B. SACHS, M.D., Professor of Diseases of the Mind and Nervous System; Consulting Neurologist to the Montefiore Home for Chronic Invalids.

THOMAS R. POOLEY, M.D., Professor of Ophthalmology; Surgeon-in-Chief of the New Amsterdam Eye and Ear Hospital; Ophthalmic Surgeon to the Sheltering Arms; Consulting Ophthalmologist to the St. Bartholomew's Hospital.

L. EMMETT HOLT, M.D., Professor of Diseases of Children; Visiting Physician to the New York Infant Asylum; Consulting Physician to the Hospital for Ruptured and Crippled.

AUGUST SEIBERT, M.D., Professor of Diseases of Children; Physician to the Children's Department of the German Dispensary.

H. MARION SIMS, M.D., Professor of Gynæcology, Gynæcologist to St. Elizabeth Hospital and New York Infant Asylum.

WILLIAM F. FLUHRER, M.D., Professor of Genito-Urinary Surgery; Surgeon to Bellevue and St. Sinai Hospitals.

HENRY C. COE, M. D., M. R. C. S. (Eng.), Professor of Gynecology; Attending Surgeon to New York Cancer Hospital; Assistant Surgeon to Woman's Hospital; Obstetric Surgeon to Maternity Hospital; Obstetrician to New York Infant Asylum; Gynecologist to Presbyterian Hospital, Out-door Department.

* Deceased.

THE NEW YORK POLYCLINIC is a School of Clinical Medicine and Surgery for *Practitioners only*. No didactic lectures are given The classes are limited. The demonstrations are made at the Polyclinic School and Hospital, and in the various Hospitals in New York City with which the Faculty are connected.

Session of 1889-90 opens Monday, September 16th, 1889. For further information and for catalogue, address

JOHN A. WYETH, M.D.,

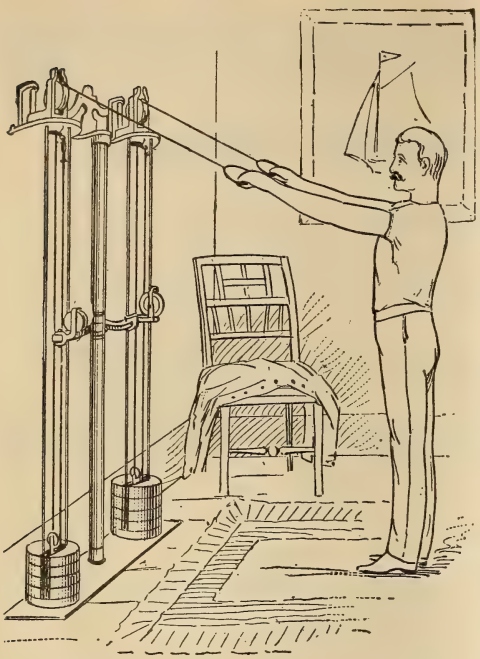
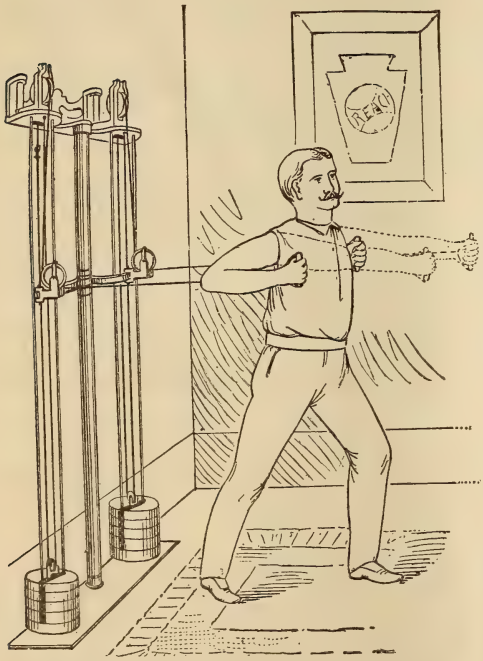
Or WILLIS O. DAVIS, Clerk,
214, 216 & 218 East 34th Street, New York City.





A. G. SPALDING & BROS.'

Gymnasium Department.

From this time henceforth the **Gymnasium** in all its important details will be a department in our business to which we shall devote especial attention.

With the addition to our own valuable patents, those of the **A. J. Reach Company,** of Philadelphia, recently purchased by us, enables us to claim the most **extensive department** of **Gymnasium Appliances in the world.**

We have been encouraged in this **important** movement by the constantly increasing demand from **Colleges, Seminaries,** and other **Educational** Institutions for Gymnasium Supplies, and henceforth we shall devote special attention to furnishing **plans, specifications,** and **estimates** to such and for **private residences** as well, and solicit correspondence with all contemplating the introduction of gymnastics for any purpose.

The Peerless Pulley Weight, illustration of which appears on this page, is a most perfect appliance for the development of the **chest** and **arms,** adjustable to the height of *any* person, and in weight from five to thirty pounds. For **man or woman** this is the peer of any method yet devised, especially for home use. Realizing the attention the **medical profession** and the **teacher,** are now giving to **healthful** exercise in **schools,** we solicit also their correspondence, and any orders, or business prceeding from such, will be gratefully received, and entitled to our best rates of discount, and will receive prompt and careful attention.

Visitors to our different establishments at **Chicago, New York,** and **Philadelphia** will always be welcome and politely served by the many efficient salesmen constantly in attendance.

A. G. SPALDING & BROS.,

CHICAGO, 108 Madison Street.
NEW YORK, 241 & 243 Broadway.
PHILADELPHIA, 1022 Market Street.
LONDON, ENGLAND, 38 Holborn Viaduct.

EXCERPTS.

PHENACETINE.—Dr. DUJARDIN-BEAUMETZ, Paris.—"It is above all as an analgesic that Phenacetine outrivals its predecessors. While it is quite as powerful as antipyrin and acetanilid, it does not cause the pain in the stomach, or the scarlatina-form rash of the former; nor does it give rise to the cyanosis of the latter. However prolonged may be its administration—and we have given it for months in doses of 1.0 to 2.0 Gm. (15 to 30 grains) per day—we have never observed any bad effect. We have used it for the relief of every form of pain (neuralgias, migraine, rheumatic pains, muscular rheumatism, acute articular rheumatism, the lightning pains of tabes, etc.) and always with the best results."

M. F. PRICE, M. D., President Southern California Medical Society.—"A patient says, 'I have headache,' and I order Phenacetine with confidence, and always with a report of relief."

THOS. W. AYERS, M. D., Jacksonville, Ala.—"As an antipyretic I have had nothing but the very best results from its use. As an antineuralgic there is no question, but it is superior to antipyrin. It is much more energetic in its action than either antipyrin or antifebrin."

SULFONAL.—HUNTER MCGUIRE, M. D., Richmond, Va.—"Has found it particularly valuable in insomnia following the use of alcohol."

HENRY M. WETHERILL, JR., M. D., Ph. G., Philadelphia.—"The almost universal report of Sulfonal is that it has little or no effect upon the vast majority of insomnous subjects save the important one of increasing, prolonging the natural tendency to sleep; that its action is not narcotic but purely hypnotic."

W. H. FLINT, M. D., New York (Discussion before N. Y. State Medical Association).—"He had used Sulfonal as being the most efficient or desirable of the new hypnotics. He had not yet seen a Sulfonal habit. There had been about eighty per cent. of successes in his cases."

JAMES STEWART, M. D., Montreal.—"Sulfonal produces no disagreeable secondary symptoms nor any unfavorable effects on the heart or circulation. Its action was by giving rest to the cells of the cerebral cortex and thereby causing sleep."

Sulfonal-Bayer has been before the Medical Profession for some time, receiving its unqualified endorsement, but the use has been limited in many cases, owing to the hesitation of the practicioner in recommending so costly a remedy.

A substantial reduction in price having been made, it enables physicians to freely prescribe it whenever indicated, and brings it within the reach of all classes of patients.

The only prominent Emulsion of Cod-Liver Oil introduced directly to the medical profession. It is advertised exclusively in medical journals.

HYDROLEINE.

(HYDRATED OIL.)

Produces rapid increase in Flesh and Strength.

FORMULA.—Each Dose contains:

Pure Cod Liver Oil.....	80 m. (drops)	Soda.....	1-3 Grains.
Distilled Water.....	35 "	Salicylic Acid.....	1-4 "
Soluble Pancreatin.....	5 Grains.	Hyocholic Acid.....	1-30 "

Recommended and Prescribed by EMINENT PHYSICIANS Everywhere. It is pleasant to the Taste and acceptable to the most delicate Stomach.

IT IS ECONOMICAL IN USE AND CERTAIN IN RESULTS.

HYDROLEINE (Hydrated Oil) is not a simple alkaline emulsion of oleum morrhuæ, but a hydro-pancreated preparation, containing acids and a small percentage of soda. Pancreatin is the digestive principle of fatty foods, and in the soluble form here used, readily converts the oleaginous material into assimilable matter, a change so necessary to the reparative process in all wasting diseases.

The following are some of the diseases in which **HYDROLEINE** is indicated:

Phthisis, Tuberculosis, Catarrh, Cough, Scrofula, Chlorosis, General Debility, etc.

TO BRAIN WORKERS of all classes, **HYDROLEINE** is invaluable,—supplying as it does, the true brain-food, and being more easily assimilated by the digestive organs than any other emulsion.

The principles upon which this discovery is based have been described in a treatise on "The Digestion and Assimilation of Fats in the Human Body," and "Consumption and Wasting Diseases," by two distinguished London physicians, which will be sent free on application.

SOLD BY DRUGGISTS GENERALLY.

C. N. CRITTENTON,

SOLE AGENT FOR THE UNITED STATES. 115 FULTON STREET, N. Y.

A Sample of Hydroleine will be sent free upon application, to any physician (enclosing business card) in the U. S.

MEDICAL AND SURGICAL REPORTER,

P. O. Box 843, Philadelphia.

WE ARE CONFIDENT THAT WE HAVE REACHED THE **Highest Degree** of Perfection *IN SOLVING THE* **INFANT FOOD PROBLEM.**

Lacto-Preparata.

A Prepared Human Milk perfectly Sterilized and especially designed for Children from birth to six or eight months of age.

Made wholly from cow's milk with the exception that the fat of the milk is partially replaced by cocoa butter. Cocoa butter is identical with milk fat in food value and digestibility, being deficient only in the principle which causes rancidity. The milk in *Lacto-Preparata* is treated with Extract of Pancreas at a temperature of 105 degrees, a sufficient length of time to render twenty-five per cent. of the casein soluble, and partially prepare the fat for assimilation. In this process the remaining portion of the casein not peptonized, is acted upon by the pancreatic ferment in such a manner as to destroy its tough tenacious character, so that it will coagulate in light and flocculent curds, like the casein in human milk.

Lacto-Preparata is not designed to replace our **Soluble Food,** but is better adapted for Infants up to eight months of age.

Carnrick's Soluble Food

Is the Nearest Approach to Human Milk that has thus far been produced, with the exception of Lacto-Preparata.

During the past season a large number of Physicians and eminent Chemists visited our Laboratory at Goshen, N. Y., and witnessed every detail connected with the production of Carnrick's Soluble Food. This invitation to witness our process is continuously open to Physicians and Chemists. All expenses from New York to Goshen and return will be paid by us. The care used in gathering the milk, its sterilization, and the cleanliness exercised in every step, cannot be excelled. Soluble Food has been improved by increasing the quantity of milk sugar and partially replacing the milk fat with cocoa butter.

SULPHO-CALCINE.

—A Positive Solvent for Diphtheritic Membrane.—

It is with great pleasure that we present to the medical profession this new and valuable combination. In over one hundred cases in the practice, and under the personal supervision of one of the most eminent and successful practitioners, in which he tested it, the membrane was dissolved in every instance, save one. This failure was not due to the want of efficacy of the preparation, but to the inability of the little patient's parents to enforce the use of it. Its action is rapid, in the majority of cases cleaning the tonsils and fauces within twenty-four hours, and in only one case of the hundred did it take forty-eight hours to accomplish its entire removal. In a case of relapse with most frightful extension of the membrane all over the whole vault of the mouth, fauces, tonsils, and larynx, accompanied with the greatest prostration, the membrane was entirely removed in forty-eight hours.

Its medical properties are antiseptic, resolvent, astringent, disinfectant and powerfully solvent.

It is entirely non poisonous and will not injure the most delicate tissues of the youngest child. It contains: Pure Oxide of Calcium; Flores Sulphuris Loti, thoroughly washed and purified; Benzo Boracic Acid, chemically pure; Oleum Eucalyptus Globulus; Oleum Gaultheria; Extractum Pancreaticus, entirely free from fat.

At a glance we see that **Sulpho-Calcine** contains, in intimate and chemical combination, all the ingredients which have proven to be of material benefit through past experience, in dissolving the membrane of Diphtheria.

Sulpho-Calcine is used either in the form of a gargle or spray. If as a gargle, it may be used pure or, which is just as well, diluted one-half with water. But if used as a spray, it must be in the concentrated form. This also applies when used with either the swab or the camel's hair brush. If any of the medicine is swallowed, no harm will ensue, but on the contrary it will help to relieve the constitutional symptoms, by its antiseptic action, as will be readily understood by a study of its component parts.

Samples of any of our preparations sent to physicians gratuitously for trial.

REED & CARNRICK, NEW YORK.

FRENCH, RICHARDS & CO.'S

COMPRESSED TABLETS,

PHENACETIN, ... 3 and 5 grains.
ANTIPYRIN. . . . . 3 and 5 grains.
PHENACETIN and SALOL, ... 2½ grains each.
QUININE, Sulphate and Bi-Sulphate, ... ½, 1, 2, 3, 4, and 5 grs.

These Compressed Tablets, or more correctly compressed powders, are made from the purest materials without the use of any excipient. Smooth and elegant in appearance; uniform in size; regular in weight. Our Compressed Tablets are distinguished by their ready solubility.

COMPRESSED ANTISEPTIC TABLETS.

Each Tablet contains:
7.3 grains, ... Hydrarg. Bichlor.
7.7 grains, ... Ammon. Chlor.

One Tablet dissolved in one pint of water will make a 1 to 1,000 solution, containing 1 part of Corrosive Sublimate in 1000 parts of water. Put up in pounds, half pounds, quarter pounds, and bottles containing respectively 100 and 25 Tablets each.

COMPRESSED ANTISEPTIC PASTILLES.

(Dr. Carl Sieler's Formulæ.)

For making Antiseptic Sprays, Nasal Wash, Mouth Wash, etc., one Tablet dissolved in four tablespoonfuls of warm water makes a solution which can be used as a spray or wash. Put up in screw-capped bottles containing 50 Pastilles each, also in one pound bottles, half-pound bottles, and quarter-pound bottles.

N. B.—These Pastilles must not be confounded with our Antiseptic Tablets, which contain Corrosive Sublimate, and are used as a germicide.

A full line of Compressed Tablets of approved formulæ always in stock.

These preparations are obtainable from the retail drug trade or can be had on application to the manufacturers,

FRENCH, RICHARDS & CO.,

PHENACETINE-BAYER IN INFLUENZA.

We have just received advices that Phenacetine-Bayer is being used to advantage both in Russia and Germany, in the treatment of the present epidemic of **INFLUENZA.** It is also being extensively employed in America for the same purpose.

Dr. A. C. HALLAM, Brooklyn, N. Y., states :—"That he has used Phenacetine extensively in the present epidemic of Influenza and has been well pleased with its effects. The rapidity with which it relieves the muscular pains has been very gratifying to him, the patient breaking out in a profuse perspiration, and in a few hours seeming relieved of all but the catarrhal symptoms, which run on and call for other treatment."—*The New York Medical Journal*, Jan. 4, 1890.

221 GENESEE STREET, UTICA, N. Y., January 6, 1890.

To the Editor of the New York Medical Journal:

SIR: I desire to echo the statement made in your last issue by Dr. A. C. Hallam, of Brooklyn, viz.: That in the treatment of fifty cases of influenza I have used phenacetine in five-grain doses repeated hourly until fifteen grains had been taken, and in *every case* the severe muscular pains and headache disappeared; following this with five-grain doses, three times daily, of the salicylate of cinchonidine. The disease disappeared upon the fourth day, and in *no cases* have there been any sequelæ either of bronchitis or pneumonia. Phenacetine, I consider superior in every way to antipyrine and acetanilide.

CHARLES R. WEED, M. D.

Phenacetine-Bayer (Para-Acetphenetidine), prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, is supplied by us in one-ounce vials and also in the form of our soluble pills, containing two, four, and five grains each. Either form may be obtained of any reputable apothecary.

W. H. Schieffelin & Co.,

Permanent Pepsin.

THE INSEPARABLE STANDARDS OF VALUE ARE PERMANENCY AND ACTIVITY.

WHEN a physician prescribes pepsin and his patient finds that it "sticks to the paper," that it forms a gummy mass "in powders," he may rely upon it that FAIRCHILD'S PEPSIN has not been dispensed; if he has ordered Fairchild's, this behavior is positive evidence that he and his patient have been the victims of "substitution."

Pepsins which are hygroscopic, which do undergo upon exposure to air the changes characteristic of peptone, are offered (in the form of scales and in powder) with pretensions to permanent quality.

If a product is sought, of well-proven permanency and of highest standard of activity, FAIRCHILD'S PEPSIN is the one which will never give cause for complaint.

Fairchild's was the original "Scale Pepsin;" the first positively "free from starch, sugar, acid, peptones or any added substance." The host of imitations of "Scale Pepsin" bear witness to the value and reputation of the original.

FAIRCHILD BROS. & FOSTER,

82 and 84 Fulton Street, New York.

A Phosphorized Cerebro-Spinant

(FRELIGH'S TONIC).

FORMULA.

Ten minims of the Tonic contain the equivalents (according to the formulæ of the U. S. P., and Dispensatory) of

Tinct. Nux Strychnos,	1	minim.
" Ignatia Amara,	1	"
" Cinchona,	4	"
" Matricaria,	1	"
" Gentian,	½	"
" Columbo,	½	"
" Phosphorus, C. P.,	1-300	gr.
Aromatics,	2	minims.

Dose: 5 to 10 drops in 2 tablespoonfuls of water.

INDICATIONS.

Paralysis, Neurasthenia, Sick and Nervous Headache, Dyspepsia, Epilepsy, Locomotor Ataxia, Insomnia, Debility of Old Age, and in the Treatment of Mental and Nervous Diseases.

A BALTIMORE PHYSICIAN, WHOSE DIPLOMA DATES FROM 1825, SAYS:

"Your combination I find vastly more effective than any tonic I have ever used. It furnishes a most powerful evidence of the vastly increased power of medicament by combination and judicious pharmaceutic preparation."

Price, One Dollar per Bottle, containing 100 of the Average 5-Drop Doses.—Physicians' single sample delivered, charges prepaid, on application. That every physician may be his own judge of its value, irrespective of the opinions of others, we make the following

SPECIAL OFFER:

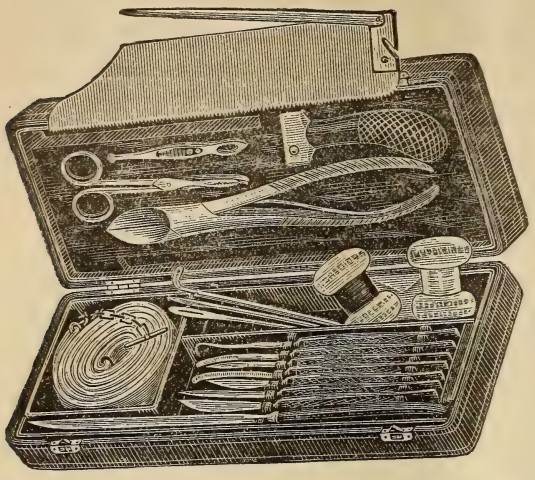
We will send to any physician, delivered, charges prepaid, on receipt of twenty-five cents, and his card or letter-head, half a dozen physicians' samples, sufficient to test it on as many cases for a week to ten days each. The Tonic is kept in stock regularly by all the leading wholesale druggists of the country. As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-lists, etc., address,

I. O. WOODRUFF & CO.,

Manufacturers of Physicians' Specialties,

No. 88 Maiden Lane, New York City.

LENTZ'S ASEPTIC COMPACT OPERATING SET, No. 10.



We have from time to time made improvements to this set and are now making a perfect aseptic set, which offers especial facilities for aseptic precautions; the blades are soldered into hollow German-silver handles nickel-plated, are light so as not to be unwieldy and admit of a firm grasp when operating.

The saw is adjusted to the handle on an entirely new principle, being made to separate easily and to facilitate thorough cleansing.

The handle is entirely of metal and fenestrated to overcome unnecessary weight.

Scissors and Forceps having French locks can be separated, and the slide can be easily removed from Artery and Needle Forceps.

Therefore, no opportunity is offered for the lodgment and development of germs.

The entire set is patterned with especial reference to facility in cleansing.

The instruments can be sterilized by placing them in boiling water, without fear of damaging them. Wood or rubber handles will not admit of this procedure. For price, see case A.

The following instruments are put up in either a fine Mahogany or Morocco case, with nickel trimmings, lined with velvet, and has an extra space for Trephine with handle, and Elevator if desired.

One Amputating Knife (6 in. blade); One Finger Knife; One Hernia Knife; One Sharp Curved Bistoury; Two Scalpels; One Tenotome; One Tenaculum; One Pair Scissors, curved or flat; One Saw (9 in. blade); One Liston's Bone Forceps, with Spring; One Artery and Needle Forceps, improved; One Esmarch's Flat Rubber Tourniquet, with Chain; One Hæmostatic Forceps; One Director, with Aneurism Needle; Two Silver Probes; Silk, Wire, Wax and Needles.

With the Sixteen Instruments Contained in this Case, any Ordinary Operation may be Performed.

SIZE, 11 INCHES LONG, 4 INCHES WIDE, 2 INCHES HIGH.

A.—German Silver aseptic Handles on Knives and Saw, ... $34 00
B.—Hard Rubber aseptic Handles on Knives and Saw, ... 29 00
C.—Ebony Handles on Knives and Saw (as shown in illustration), ... 25 00
Either Set, with Trephine and Elevator in addition, ... 4 65

ANTIFEBRIN IN INFLUENZA!

This use of this Renowned ANTIPYRETIC, ANODYNE, SEDATIVE and NERVINE seems suggested by the following Judgments passed on it by Reputed Authorities in Symptomatically *Allied Complaints:*—

As an **Antifebrile** Dose:—2 to 4 grains *single;* 16 to 32 grains *daily.*—(WEINSTEIN, Vienna.)

As an **Anodyne** and **Nervine** Dose in severest Neurotic and Secondary Pains:—8 to 16 grains, *one to four times per day.*—(DEMIEVILLE, Lausanne.)

Mode of Administration:

"Even the *initial dose* gave evident relief; commonly within half an hour. If this did not suffice to break up the symptoms materially, a second dose followed in an hour or two; at the very utmost a third one was given the same day.

"The remedy was effective and well tolerated at all times; at all hours of the day; on an empty or a full stomach; even during menstruation.

"The form of exhibition was that of *powders*, wrapped in *wafers*. The readier solubility of the Antifebrin in Alcohol indicates the advisability of following the dose by a small draught of Wine or Brandy."—(ORT, Prague.)

ANOTHER MODE OF ADMINISTRATION:—*Dissolve* your Dose (4 to 12 grains) of **ANTIFEBRIN** in ½–1 ounce (1 to 2 Tablespoonfuls) of *Boiling Water*,—stirring for a minute or two, until dissolved. Allow the Solution *to cool down* to about 104 degrees F. (being just comfortably warm) and sweeten to taste, *Before Taking!*—NO ALCOHOL, WINE, or LIQUOR needed with it when thus prepared.

ANTIFEBRIN

was found **Superior** to the **Following** Remedies in **Efficacy**, or in Safety, or in **Both**:—

Antipyrine,—*Quinine*,—*Morphine*,—*Opium*,—CHLORAL HYDRATE—ACONITE,—CAFFEINE,—KAIRINE,—*Salicylic Acid*,—CARBOLIC ACID,—*Bromides*,—IODIDES.

Among the Medical Authorities from whose Clinical and other Published Reports the above-stated PREFERENCES OF ANTIFEBRIN OVER OTHER REMEDIES have been drawn, are the following:

HARE, University of Pennsylvania;—DUJARDIN-BEAUMETZ, Paris;—HERCZEL, Heidelberg;—MURRAY, *Brit. Med. Journal;*—PAVAIVAJNA, *Centralblatt für die gesammte Therapie;*—BARR, Bridgeport, Ill.;—KELL, Delphos, O.;—HAY, New York;—HAAS, Prague.

Antifebrin was also *found to be:*

"Thoroughly *reliable* as an ANTIPYRETIC."—(DEMME, Berne.)

"*Not only* powerfully ANTITHERMIC, but also a most *useful* NERVINE."—(LEPINE, Lyons.)

"A *powerful, safe*, and *certain* ANTITHERMIC agent."—(EVANS, Easton, Pa.)

"*Complete* ANALGETIC effect in nine cases out of every ten."—(FISCHER, Cannstatt.)

RABUTEAU'S DRAGEES OF IRON

Laureate of the Institute of France.—Prize in Therapeutics.

The studies made by the Physicians of the Hospitals have demonstrated that the **Genuine Dragees of Iron of Rabuteau** are superior to all other preparations of Iron in cases of *Chlorosis, Anæmia, Leucorrhœa, Debility, Exhaustion, Convalescence, Weakness of Children*, and the maladies caused by the Impoverishment and Alteration of the blood after periods of fatigue, watching, and excesses of any kind.

TAKE 4 TO 6 DRAGEES DAILY.

Rabuteau's Elixir of Iron is recommended to those persons who may be unable to swallow the Dragees. Dose —*A small wineglassful with meals.*

Rabuteau's Syrup of Iron is specially designed for children. Chalybeate medication, by means of **Rabuteau's Iron**, is the most economical and the most rational known to therapeutics.

No constipation, no diarrhœa, complete assimilation.

Take only the GENUINE IRON OF RABUTEAU of

CLIN & CO., Paris.

SOLUTION OF THE SALICYLATE OF SODA OF DOCTOR CLIN.

Laureate of the Paris Faculty of Medicine (MONTYON PRIZE).

Dr. Clin's Solution, always identical in its composition, and of an agreeable taste, permits the easy administration of *pure Salicylate of Soda*, and the variation of the dose in accordance with the indications presented.

"The *Salicylate of Soda* used by **Clin** is of perfect purity, "and is prepared with the greatest care; it is a medicament "in which we may have every confidence."

—*Paris Society of Medicine, Meeting of Feb. 8th, 1879.*

Clin's Solution, very exactly mixed, contains: 2 grammes of *Salicylate of Soda* per tablespoonful, 50 centigrammes of *Salicylate of Soda* per teaspoonful.

"Aconitine produces marvelous effects in the treatment "of *facial neuralgias* when they are not symptomatic of "intracranial tumor."—*Society of Biology of Paris, Meeting* "*of the 28th February, 1880.*

DOSE—Take 3 to 6 pills during the twenty-four hours.

ACCEPT ONLY THE GENUINE MOUSSETTE PILLS OF

CLIN & CO.,—Paris.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the **three** Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PARIS.—22 RUE DROUOT.—PARIS.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

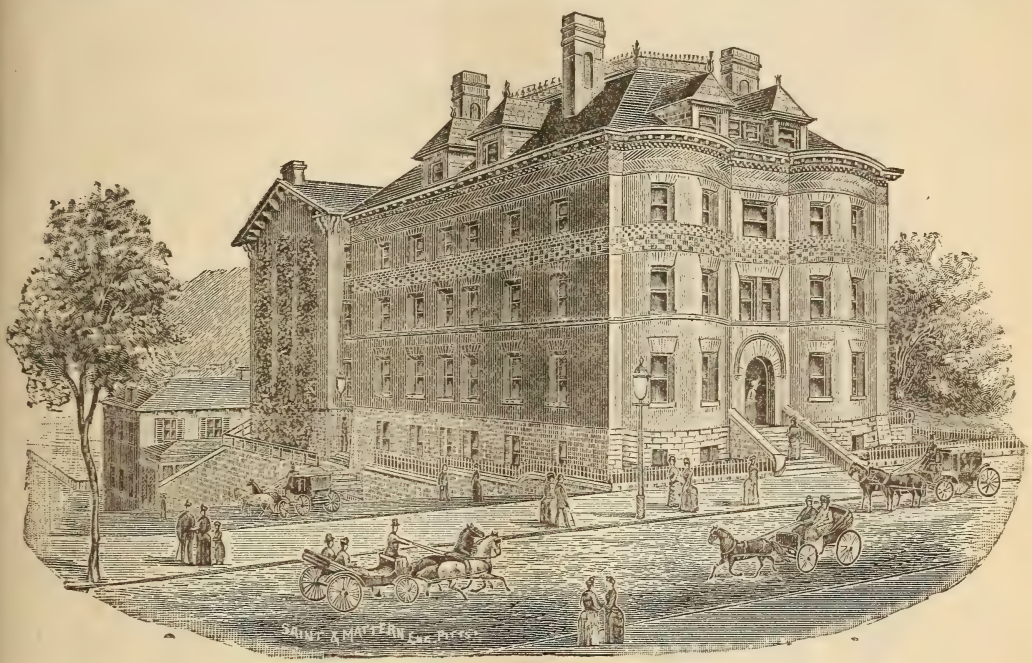
DR. R. S. SUTTON'S

Sanatorium for Diseases of Women.



Seventh Year Opens September 1, 1889.

ALLEGHENY CITY, PA.

This Institution is located on high ground, and overlooks the Allegheny, Monongahela and Ohio rivers; it commands a view of the city of Pittsburgh, and its picturesque surroundings. The building is large and beautiful, it is provided with every modern convenience, the halls are heated by steam, the rooms are commodious, well lighted and ventilated, and heated by open grates. The house is provided with a private parlor and reading-room for patients. The dining-room is large, handsomely finished, and furnished with small tables, securing privacy at meals for those who do not care to have meals served in their own rooms. Patients can be as secluded, should they desire it, as in a well appointed hotel. Each patient is examined by Dr. Sutton, and receives his daily personal attention, while Dr. J. H. Williamson, a physician of ample hospital experience, resides in the In-titution, and has, under Dr. Sutton, the immediate care of the patients. The Institution accommodates 25 patients, and is equal in comfort to the best hotels.

Electricity, baths, douches, massage, local treatment, general medication and surgical operations are resorted to according to the requirements of each patient.

For further information address the Matron

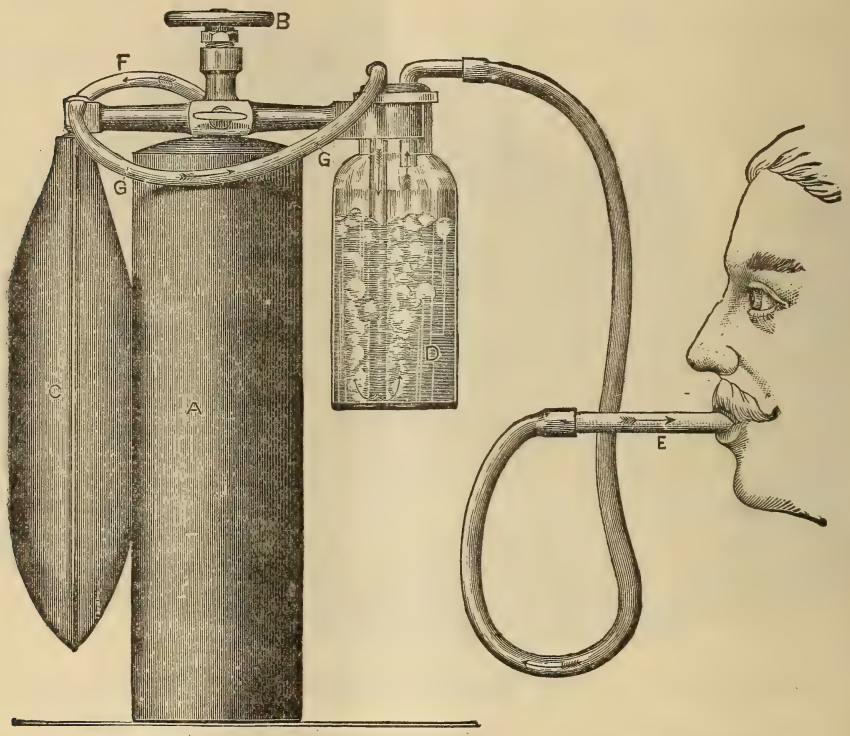
INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

CALIFORNIA VINTAGE CO.

21 PARK PLACE. N.Y.

Geo Hamlin Prest. Chas Roome Parmele Treas.

GENTLEMEN:

The Case of your wines sent me for analysis by Dr. A. L. Hummel, of the "Annals of Hygiene," containing specimens of your La Rosa Zinfandel, Mataro, Riesling, Royal Tokay, and Royal Grape Brandy, has been duly received.

I have examined them for the common contaminants of wine; to wit: Sulphurous acid and sulphites, salicylic acid, fuchsin, lead salts, etc., none of which I found present therein.

I have also determined their alcoholic strength, extractives, and ashes, and found them to correspond strictly in this respect with the standard of pure and natural wines, which cannot be said of many of the imported wines.

As a native of a wine-producing country, I consider myself somewhat of a judge of wines, and regard your products as comparing more than favorably with most of the wines from abroad which are sold at higher prices, so much so that I enclose within my order for fifty bottles of La Rosa Zinfandel, which I expect to use hereafter exclusively at my table.

Very Respectfully,

L. WOLFF, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

PARIS MEDAL

TO

WILLIAM R. WARNER & CO.

W. R. WARNER & CO. have received a Silver Medal at the Paris World's Fair, being the highest of its kind, in recognition of the following claims:

First.—W. R. Warner & Co.'s Pills, quick solubility and accuracy

Second.—Reliability and permanency unsurpassed. Also for Warner & Co.'s Effervescent Salts.

First.—Superior effervescing properties.

Second.—General elegance, excellence, and stability.

PHYSICIANS SHOULD BE CAREFUL TO SPECIFY WARNER & CO.

☞The coating of the following pill will dissolve in 4½ minutes.☜

PIL: CHALYBEATE COMP.

(WARNER & CO.)

Nux Vomica is added as an ingredient to Pill Chalybeate to increase the tonic effect when desired. Composition of each Pill.—℞ (Chalybeate Mass.), Carb. Protoxide of Iron, gr. 2½, Ext. Nuc. Vom. gr. 1-6.

DOSE—1 to 3 Pills.

Most advantageously employed in the treatment of Anæmia, Chlorosis, Phthisis, Scrofula, Loss of Appetite, etc.

PIL: ANTISEPTIC.

Each Pill contains: Sulphite Soda, 1 gr. Salicylic Acid, 1 gr. Ext. Nuc. Vomica, ¼ gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic is prescribed with great advantage in cases of Dyspepsia attended with acid stomach and enfeebled digestion following excessive indulgence in eating or drinking. It is used with advantage in Rheumatism.

Prepared by WM. R. WARNER & CO.

PIL: ANTISEPTIC COMP.

(WARNER & CO.)

Each pill contains: Sulphite Soda, 1 gr. Salicylic Acid, 1 gr. Ext. Nuc. Vomica, ⅛ gr. Powd. Capsicum, 1-10 gr. Conc't Pepsin, 1 gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic Comp. are prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food.

Supplied upon physician's prescription by all leading druggists. Take no substitute.

1228 MARKET ST., Phila. 18 LIBERTY ST., New York.

The Acutely Ill.

When a patient is acutely ill, the digestive powers share in the general condition, and consequently the food supplied should be of the most easily assimilable character. The predigestion of starchy matters outside the body, as in MELLIN'S FOOD, is necessary, and the soluble carbohydrates of which this food consists, soluble because predigested, form the true food of the acutely ill.—J. MILNER FOTHERGILL, M.D., Edin.

A sample of MELLIN'S FOOD ***will be sent to any physician, free of expense, upon application.***

Doliber-Goodale Co., Boston, Mass.

Apollinaris

"THE QUEEN OF TABLE WATERS."

The filling at the Apollinaris Spring (Rhenish Prussia), amounted to

11,894,000 BOTTLES IN **1887,**
12,720,000 BOTTLES IN **1888** AND
15,822,000 BOTTLES IN **1889.**

"The annual consumption of this favorite beverage affords a striking proof of the widespread demand which exists for table water of absolute purity, and it is satisfactory to find that, wherever one travels, in either hemisphere, it is to be met with; it is ubiquitous, and should be known as the cosmopolitan table water. 'Quod ab omnibus, quod ubique.'"—BRITISH MEDICAL JOURNAL.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the **HUNGARIAN APERIENT WATER SOLD BY THE COMPANY** from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the **HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.**

THE VALUE OF NUTRITION IN DISEASE.

All physicians who have ever used Murdock's Liquid Food and Suppositories recognize their value over all other foods, in breaking up disease and building up the patients after disease, preventing a relapse, **as the same results are obtained as in surgery.** Its value in surgical cases we illustrate by the records of the different cities and of Murdock's Free Surgical Hospital for Women, which is the largest in the United States. It contains 114 beds, every bed free, including operation, the operations ranging from 1000 to 1200 yearly, representing 90 of the worst classes known in surgery. Among these cases we have had **Cancer of uterus** (*Kolpo-hysterectomy*), 13; **Salpingitis** (*Tait's operation*), 31; **Fibroid of uterus** (*abdominal hysterectomy*), 19; **Ventral operation, hernia,** (*abdominal section*), 12; **Cancer of bowel** (*incision*), 2; **Parovarian cyst, 6; Papillomatous cyst** (*extirpation*), 4; **Tubercular peritonitis** (*incision*), 1, **Ovarian cystoma 27; Nymphomania** (*Battey*), 1; **Exploratory abdominal incisions, 12; Fibroid with abdominal abscess** (*Hegar*), 2; **Hysterorraphy, 2; Dermoid cyst, 3; Cirrhotic ovaries,** (*Battey*), 4; **Fibroid uterus** (*Hegar*), 6; **Hystero-epilepsy** (*Battey*), 1; **Haemato-Salpinx** (*Tait*), 5; **Rupture of intestine into vagina, 1; Dislocated kidney, 2; Fibroid tumor abdominal wall, 1; Resection of intestine** (*Senn*), 1; **Ruptured perineum, 294.** Patients are in the Hospital 8 days before and 26 days after operation, on an average.

In Boston, last year, 42 deaths were from Cancer in the Breast. In Murdock's Hospital, 35 such cases were operated on without a death, the patients remaining in the Hospital, on an average, 18 days.

Mortality	in Boston,	25.60	per 1000.
"	of Women in Boston,	29,00	" "
"	**in Murdock's Free Surgical Hospital,**	**5.00**	" "
"	New York,	26.32	" "
"	Philadelphia,	20.00	" "
"	Chicago,	20.90	" "
"	St. Louis,	20.49	" "

showing our mortality is only one-sixth as great as of those in health. As good results were obtained in our General Hospital, which we kept open 27 months, **thus showing the value of nutrition as found in Murdock's Liquid Food, and so recognized by the British and American Medical Associations,** before which essays were read and discussed, and it is the only Raw food preparation on which essays were ever read.

Physicians are invited to visit our Hospitals and Works, also to send in patients and to be present at the operations. For any physician who has not used our Liquid Food (and Suppositories for adults and infants), we will deliver free samples to any express company in Boston.

When babies do not thrive, never change their food, but add five or more drops at each feeding of Murdock's Liquid Food, and their lost or needed vitality will be restored in less than thirty days. It is invaluable when weaning babies or when teething. If mothers will take one teaspoonful to a tablespoonful before each meal and on retiring, they will receive as much benefit as the baby.

Murdock Liquid Food Co., Boston.

GOUDRON DE BLOUNT

PREPARED FROM THE GENUINE CAROLINA TAR.

DOSE.—One fluid drachm four or more times a day (as indicated), either full strength, diluted, or, in combination.

INDICATIONS.—Chronic and acute affections of the Air Passages, Coughs, Colds, Bronchitis, Asthma and Consumption.

WILLIAM MURRELL, M.D., F.R.C.P.,

Lecturer on Pharmacology and Therapeutics at the Westminster Hospital; Examiner in Materia Medica to the Royal College of Physicians of London; Fellow of the Medico-Chirurgical College of Philadelphia,

Says:—"I have used with success 'Goudron de Blount.' The results have been good, and the preparation is popular with patients."

PREPARED EXCLUSIVELY FOR PHYSICIANS' PRESCRIPTIONS BY

R. E. BLOUNT, 33 RUE ST. ROCH, PARIS.

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.

Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N. Y.

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

ALETRIS CORDIAL

UTERINE TONIC AND RESTORATIVE.

Prepared from the Aletris Farinosa or True Unicorn and Aromatics.

INDICATIONS.

Amenorrhea, Dysmenorrhea, Leucorrhea, Prolapsus Uteri, Sterility, to Prevent Miscarriage, Etc.

DOSE:—ONE TEASPOONFUL THREE OR FOUR TIMES A DAY.

UNRIVALED AS A UTERINE TONIC IN IRREGULAR, PAINFUL, SUPPRESSED AND EXCESSIVE MENSTRUATION.

It Restores Normal Action to the Uterus, and Imparts Vigor to the Entire Uterine System.

☞Where women have miscarried during previous pregnancies, or in any case where miscarriage is feared, the ALETRIS CORDIAL is indicated, and should be continuously administered during entire gestation.

CHAS. CLAY, M. R. C. S., Manor House, Dewsbury, England, says:—I find Aletris Cordial (Rio) is of great service in threatened miscarriage.

FRANCIS E. CANE, L. R. C. S., &c., Leeds, England, says:—I have tried the Aletris Cordial (Rio) in two cases of long standing dysmenorrhea, with excellent results. One of these patients has spent a week in bed every month for two years. After all the usual remedies, I put her on Aletris Cordial, and for the last two periods she has been out and about all the time.

L. M. WATSON, M. D., Delhi, Ills., says:—I have used Aletris Cordial (Rio) in cases of dysmenorrhea, suppressed menses and threatened miscarriage, and also, combined with Celerina, as a tonic after confinement, with the happiest results, and now I am using it on a case of leucorrhea, with injections of S. H. Kennedy's Extract of Pinus Canadensis, and it is acting like a charm.

P. H. OWEN, M. D., Morganville, Ala., says:—I have prescribed Aletris Cordial (Rio) in several cases with the most satisfactory results, and regard it as the best uterine tonic I have met with in a professional experience of over twenty-five years. In cases of threatened miscarriage it acts like a charm. Would recommend its continuous administration in all cases when there is any indication of miscarriage.

DR. W. BERTHELOT, Santander, Spain, says:—I have tried the Aletris Cordial (Rio), and it has seemed to me to be useful, especially in cases of dysmenorrhea.

DR. RASQUINET, Jupile, near Liege, Belgium, says:—I tried Aletris Cordial (Rio) in the case of a woman who had had several miscarriages at the end of five months, and who is now again pregnant, having reached the seventh month, thanks to Aletris Cordial.

R. REECE, M. R. C. S., Walton-on-Thames, England, says:—Aletris Cordial (Rio) in painful menstruation is most valuable. A wife of a minister suffered much, and had had three miscarriages. I prescribed Aletris Cordial. She has for the first time, gone her full time, and was safely confined with a male child.

J. T. COLLIER, M. D., Brooks, Me., says:—I have used your Aletris Cordial (Rio) in cases of females at the menopause. Consider it one of the finest remedies for these cases.

DR. GORDILLON, St. Amand, France, says: I have tried the Aletris Cordial (Rio) in a case of dysmenorrhea. The result I obtained from the use of your preparation was excellent, better than I had obtained in the same patient by prescribing the usual remedies employed in such cases.

W. F. TOOMBS, M. D., Morrillton, Ark., says:—I have used a great deal of your Aletris Cordial (Rio) and I find it all you claim for it in amenorrhea, dysmenorrhea, metritis, leucorrhea; I don't think it has an equal. I have used it in two cases of threatened miscarriage and the trouble was obviated. For a general Uterine Tonic I know of nothing superior.

R. D. PATTERSON, L. R. C. S. &c., Medical Officer, Caledon Dispensary, Co. Tyrone, Ireland, says:—I have very great pleasure in testifying to the very high opinion I hold of Aletris Cordial (Rio) in threatened miscarriage.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

E. FOUGERA & CO., 30 North William St., New York,

Sole Agents for the above Preparations.

DOCTOR, thousands of Infants die from Artificial Feeding who would live and thrive if their Mothers were enabled to yield good milk copiously by using Nutrolactis, the Galactagogue.

WESTERN PENNSYLVANIA MEDICAL COLLEGE

CITY OF PITTSBURGH.

SESSIONS OF 1889—90.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. J. W. J. MCKENNAN.

Business correspondence should be addressed to
PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

NATIONAL MEDICAL COLLEGE.

MEDICAL DEPARTMENT OF THE

COLUMBIAN UNIVERSITY,

WASHINGTON, D. C.

The 68th Annual Session will begin October 7th and end March 1st. Graded three years' course required. Women admitted. Professors: J. F. Thompson, W. W. Johnston, A. F. A. King, E. T. Fristoe, Wm. Lee, D. W. Prentiss, D. K. Shute.

For circulars, address

A. F. A. KING, M. D., DEAN, 726 THIRTEENTH ST., N. W., WASHINGTON D. C.

DETROIT COLLEGE OF MEDICINE.

SESSION 1889-90.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, Sept. 25, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins April 2d, 1890; and closes June 11th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

Gymnasium Department.

From this time henceforth the **Gymnasium** in all its important details will be a department in our business to which we shall devote especial attention.

With the addition to our own valuable patents, those of the **A. J. Reach Company**, of Philadelphia, recently purchased by us, enables us to claim the most **extensive department** of **Gymnasium Appliances in the world**.

We have been encouraged in this **important** movement by the constantly increasing demand from **Colleges, Seminaries,** and other **Educational** Institutions for Gymnasium Supplies, and henceforth we shall devote special attention to furnishing **plans, specifications,** and **estimates** to such and for **private residences** as well, and solicit correspondence with all contemplating the introduction of gymnastics for any purpose.

The Peerless Pulley Weight, illustration of which appears on this page, is a most perfect appliance for the development of the **chest** and **arms,** adjustable to the height of *any* person, and in weight from five to thirty pounds. For **man or woman** this is the peer of any method yet devised, especially for home use. Realizing the attention the **medical profession** and the **teacher,** are now giving to **healthful** exercise in **schools,** we solicit also their correspondence, and any orders, or business prceeding from such, will be gratefully received, and entitled to our best rates of discount, and will receive prompt and careful attention.

Visitors to our different establishments at **Chicago, New York,** and **Philadelphia** will always be welcome and politely served by the many efficient salesmen constantly in attendance.

A. G. SPALDING & BROS.,

LONDON, ENGLAND, 38 Holborn Viaduct.

EXCERPTS.

PHENACETINE.—Dr. DUJARDIN-BEAUMETZ, Paris.—"It is above all as an analgesic that Phenacetine outrivals its predecessors. While it is quite as powerful as antipyrin and acetanilid, it does not cause the pain in the stomach, or the scarlatina-form rash of the former; nor does it give rise to the cyanosis of the latter. However prolonged may be its administration—and we have given it for months in doses of 1.0 to 2.0 Gm. (15 to 30 grains) per day—we have never observed any bad effect. We have used it for the relief of every form of pain (neuralgias, migraine, rheumatic pains, muscular rheumatism, acute articular rheumatism, the lightning pains of tabes, etc.) and always with the best results."

M. F. PRICE, M. D., President Southern California Medical Society.—"A patient says, 'I have headache,' and I order Phenacetine with confidence, and always with a report of relief."

THOS. W. AYERS, M. D., Jacksonville, Ala.—"As an antipyretic I have had nothing but the very best results from its use. As an antineuralgic there is no question, but it is superior to antipyrin. It is much more energetic in its action than either antipyrin or antifebrin."

SULFONAL.—HUNTER MCGUIRE, M. D., Richmond, Va.—"Has found it particularly valuable in insomnia following the use of alcohol."

HENRY M. WETHERILL, JR., M. D., Ph. G., Philadelphia.—"The almost universal report of Sulfonal is that it has little or no effect upon the vast majority of insomnous subjects save the important one of increasing, prolonging the natural tendency to sleep; that its action is not narcotic but purely hypnotic."

W. H. FLINT, M. D., New York (Discussion before N. Y. State Medical Association).—"He had used Sulfonal as being the most efficient or desirable of the new hypnotics. He had not yet seen a Sulfonal habit. There had been about eighty per cent. of successes in his cases."

JAMES STEWART, M. D., Montreal.—"Sulfonal produces no disagreeable secondary symptoms nor any unfavorable effects on the heart or circulation. Its action was by giving rest to the cells of the cerebral cortex and thereby causing sleep."

Sulfonal-Bayer has been before the Medical Profession for some time, receiving its unqualified endorsement, but the use has been limited in many cases, owing to the hesitation of the practicioner in recommending so costly a remedy.

A substantial reduction in price having been made, it enables physicians to freely prescribe it whenever indicated, and brings it within the reach of all classes of patients.

73 Trinitrin 1-150 grain.
74 Trinitrin 1-200 grain.

We claim for our Hypodermic Tablets:

Absolute Accuracy of Dose.
Ready and Entire Solubility.
Perfect Preservation of the Drug.

Their convenience and utility will at once be apparent on examination.

They are put up in Cylindrical Tubes, convenient for carrying in Hypodermic or Pocket case, ten tubes in a box, with twenty tablets in each tube.

NOTE.—It will only be necessary in ordering to specify the numbers, as above. Wyeth's Manufacture. These Tablets will be sent by mail, on receipt of the proper amount.

PHILADELPHIA, PA.

Doctor:

Did you ever think of the philosophy of a course of treatment by the Hypophosphites of Lime and Soda?

It affords a most beautiful study in physiological repair. It is firmly based on Virchow's principles of cellular pathology.

When a plant is not thriving well the horticulturist treats it, not with medicine, but with its appropriate plant food. We should draw a lesson from this more often than we do.

Thousands of cases die every year, and thousands of others pass into hopeless invalidism, simply because the first perversions of nutrition are not corrected by supplying the system in abundance with the appropriate tissue food. As lime and soda are so abundantly found in animal tissues, and are necessary to unite with the organic elements in the formation of new cells, it must be evident that most of the departures from health are due to a lack of the proper proportion of these elements supplied to the tissues.

These errors of nutrition, if taken at the beginning, are quickly and easily corrected; but if they are allowed to go on until grave anatomical lesions are produced, or profound alterations of the nervous system are established, the cure must be slow and gradual, yet none the less sure if the treatment be continued.

A very important particular in prescribing the Hypophosphites of Lime and Soda is to secure their absolute chemical purity. This is secured and guaranteed in McArthur's Syrup. Its results are uniform and reliable. It is not filled up and complicated with the delusive irritant "tonics."

If at any time you want any other ingredient used it can be added to the prescription.

In McArthur's Syrup you get the chemically pure Hypophosphites of Lime and Soda. It is put up for use in physicians' prescriptions, hence has no labels or directions on the bottle.

Our valuable treatise on "The Curability and Treatment of Consumption" will be sent free to any physician requesting it. Also one bottle of McArthur's Syrup, if you will agree to pay express charges.

McARTHUR HYPOPHOSPHITE CO.,
BOSTON, MASS.

SAVE MONEY

IN BUYING BOOKS.

PHENACETINE-BAYER IN INFLUENZA.

We have just received advices that Phenacetine-Bayer is being used to advantage both in Russia and Germany, in the treatment of the present epidemic of **INFLUENZA.** It is also being extensively employed in America for the same purpose.

Dr. A. C. HALLAM, Brooklyn, N. Y., states :—"That he has used Phenacetine extensively in the present epidemic of Influenza and has been well pleased with its effects. The rapidity with which it relieves the muscular pains has been very gratifying to him, the patient breaking out in a profuse perspiration, and in a few hours seeming relieved of all but the catarrhal symptoms, which run on and call for other treatment."—*The New York Medical Journal*, Jan. 4, 1890.

221 GENESEE STREET, UTICA, N. Y., January 6, 1890.

To the Editor of the New York Medical Journal:

SIR: I desire to echo the statement made in your last issue by Dr. A. C. Hallam, of Brooklyn, viz.: That in the treatment of fifty cases of influenza I have used phenacetine in five-grain doses repeated hourly until fifteen grains had been taken, and in *every case* the severe muscular pains and headache disappeared; following this with five-grain doses, three times daily, of the salicylate of cinchonidine. The disease disappeared upon the fourth day, and in *no cases* have there been any sequelæ either of bronchitis or pneumonia. Phenacetine, I consider superior in every way to antipyrine and acetanilide.

CHARLES R. WEED, M. D.

Phenacetine-Bayer (Para-Acetphenetidine), prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, is supplied by us in one-ounce vials and also in the form of our soluble pills, containing two, four, and five grains each. Either form may be obtained of any reputable apothecary.

W. H. Schieffelin & Co.,
170 & 172 WILLIAM STREET,
NEW YORK.

The Acutely Ill.

When a patient is acutely ill, the digestive powers share in the general condition, and consequently the food supplied should be of the most easily assimilable character. The predigestion of starchy matters outside the body, as in MELLIN'S FOOD, is necessary, and the soluble carbohydrates of which this food consists, soluble because predigested, form the true food of the acutely ill.—J. MILNER FOTHERGILL, M.D., Edin.

A sample of MELLIN'S FOOD *will be sent to any physician, free of expense, upon application.*

Doliber-Goodale Co., Boston, Mass.

A Phosphorized Cerebro-Spinant

(FRELIGH'S TONIC).

FORMULA.

Ten minims of the Tonic contain the equivalents (according to the formulæ of the U. S. P., and Dispensatory) of

Tinct. Nux Strychnos,	1 minim.
" Ignatia Amara,	1 "
" Cinchona,	4 "
" Matricaria,	1 "
" Gentian,	½ "
" Columbo,	½ "
" Phosphorus, C. P.,	1-300 gr.
Aromatics,	2 minims.

Dose: 5 to 10 drops in 2 tablespoonfuls of water.

INDICATIONS.

Paralysis, Neurasthenia, Sick and Nervous Headache, Dyspepsia, Epilepsy, Locomotor Ataxia, Insomnia, Debility of Old Age, and in the Treatment of Mental and Nervous Diseases.

A BALTIMORE PHYSICIAN, WHOSE DIPLOMA DATES FROM 1825, SAYS:

"Your combination I find vastly more effective than any tonic I have ever used. It furnishes a most powerful evidence of the vastly increased power of medicament by combination and judicious pharmaceutic preparation."

Price, One Dollar per Bottle, containing 100 of the Average 5-Drop Doses.—Physicians' single sample delivered, charges prepaid, on application. That every physician may be his own judge of its value, irrespective of the opinions of others, we make the following

SPECIAL OFFER:

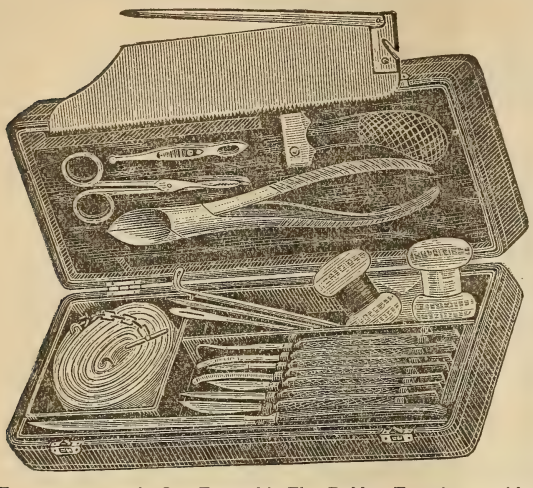
We will send to any physician, delivered, charges prepaid, on receipt of twenty-five cents, and his card or letter-head, half a dozen physicians' samples, sufficient to test it on as many cases for a week to ten days each. The Tonic is kept in stock regularly by all the leading wholesale druggists of the country. As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-lists, etc., address,

I. O. WOODRUFF & CO.,

Manufacturers of Physicians' Specialties,

No. 88 Maiden Lane, New York City.

LENTZ'S ASEPTIC COMPACT OPERATING SET, No. 10.



We have from time to time made improvements to this set and are now making a perfect aseptic set, which offers especial facilities for aseptic precautions; the blades are soldered into hollow German-silver handles, nickel-plated, are light so as not to be unwieldy and admit of a firm grasp when operating.

The saw is adjusted to the handle on an entirely new principle, being made to separate easily and to facilitate thorough cleansing.

The handle is entirely of metal and fenestrated to overcome unnecessary weight.

Scissors and Forceps having French locks can be separated, and the slide can be easily removed from Artery and Needle Forceps.

Therefore, no opportunity is offered for the lodgment and development of germs.

The entire set is patterned with especial reference to facility in cleansing.

The instruments can be sterilized by placing them in boiling water, without fear of damaging them. Wood or rubber handles will not admit of this procedure. For price, see case A.

The following instruments are put up in either a fine Mahogany or Morocco case, with nickel trimmings, lined with velvet, and has an extra space for Trephine with handle, and Elevator if desired.

One Amputating Knife (6 in. blade); One Finger Knife; One Hernia Knife; One Sharp Curved Bistoury; Two Scalpels; One Tenotome; One Tenaculum; One Pair Scissors, curved or flat; One Saw (9 in. blade); One Liston's Bone Forceps, with Spring; One Artery and Needle Forceps, improved; One Esmarch's Flat Rubber Tourniquet, with Chain; One Hæmostatic Forceps; One Director, with Aneurism Needle; Two Silver Probes; Silk, Wire, Wax and Needles.

With the Sixteen Instruments Contained in this Case, any Ordinary Operation may be Performed.

SIZE, 11 INCHES LONG, 4 INCHES WIDE, 2 INCHES HIGH.

A.—German Silver aseptic Handles on Knives and Saw, ... **$34 00**
B.—Hard Rubber aseptic Handles on Knives and Saw, ... **29 00**
C.—Ebony Handles on Knives and Saw (as shown in illustration), ... **25 00**
Either Set, with Trephine and Elevator in addition, ... **4 65**

DISCOUNT 25 PER CENT. TO PHYSICIANS. Our Catalogue of 260 pages will be sent on receipt of 10 cts. for postage.

ANTIFEBRIN IN INFLUENZA!

This use of this Renowned ANTIPYRETIC, ANODYNE, SEDATIVE and NERVINE seems suggested by the following Judgments passed on it by Reputed Authorities in Symptomatically *Allied Complaints:*—

As an **Antifebrile** Dose:—2 to 4 grains *single;* 16 to 32 grains *daily.*—(WEINSTEIN, Vienna.)

As an **Anodyne** and **Nervine** Dose in severest Neurotic and Secondary Pains:—8 to 16 grains, *one to four times per day.*—(DEMIEVILLE, Lausanne.)

Mode of Administration:

"Even the *initial dose* gave evident relief; commonly within half an hour. If this did not suffice to break up the symptoms materially, a second dose followed in an hour or two; at the very utmost a third one was given the same day.

"The remedy was effective and well tolerated at all times; at all hours of the day; on an empty or a full stomach; even during menstruation.

"The form of exhibition was that of *powders*, wrapped in *wafers*. The readier solubility of the Antifebrin in Alcohol indicates the advisability of following the dose by a small draught of Wine or Brandy."—(OTT, Prague.)

ANOTHER MODE OF ADMINISTRATION:—*Dissolve* your Dose (4 to 12 grains) of **ANTIFEBRIN** in 1/2–1 ounce (1 to 2 Tablespoonfuls) of *Boiling Water*,—stirring for a minute or two, until dissolved. Allow the Solution *to cool down* to about 104 degrees F. (being just comfortably warm) and sweeten to taste, *Before Taking!*—NO ALCOHOL, WINE, or LIQUOR needed with it when thus prepared.

ANTIFEBRIN

was found **Superior** to the **Following** Remedies in **Efficacy**, or in Safety, or in **Both**:—

Antipyrine,—*Quinine*,—*Morphine*,—*Opium*,—CHLORAL HYDRATE—ACONITE,—CAFFEINE,—KAIRINE,—*Salicylic Acid*,—CARBOLIC ACID,—*Bromides*,—IODIDES.

Among the Medical Authorities from whose Clinical and other Published Reports the above-stated PREFERENCES OF ANTIFEBRIN OVER OTHER REMEDIES have been drawn, are the following:

HARE, University of Pennsylvania;—DUJARDIN-BEAUMETZ, Paris;—HERCZEL, Heidelberg;—MURRAY, *Brit. Med. Journal;*—PAVAIVAJNA, *Centralblatt für die gesammte Therapie;*—BARR, Bridgeport, Ill.;—KELL, Delphos, O.;—HAY, New York;—HAAS, Prague.

Antifebrin was also *found to be:*

"Thoroughly *reliable* as an ANTIPYRETIC."—(DEMME, Berne.)

"*Not only* powerfully ANTITHERMIC, but also a most *useful* NERVINE."—(LEPINE, Lyons.)

"A *powerful, safe*, and *certain* ANTITHERMIC agent."—(EVANS, Easton, Pa.)

"*Complete* ANALGETIC effect in nine cases out of every ten."—(FISCHER, Cannstatt.)

RABUTEAU'S DRAGEES OF IRON

Laureate of the Institute of France.—Prize in Therapeutics.

The studies made by the Physicians of the Hospitals have demonstrated that the **Genuine Dragees of Iron of Rabuteau** are superior to all other preparations of Iron in cases of *Chlorosis, Anæmia, Leucorrhœa, Debility, Exhaustion, Convalescence, Weakness of Children*, and the maladies caused by the Impoverishment and Alteration of the blood after periods of fatigue, watching, and excesses of any kind.

TAKE 4 TO 6 DRAGEES DAILY.

Rabuteau's Elixir of Iron is recommended to those persons who may be unable to swallow the Dragees. Dose —*A small wineglassful with meals.*

Rabuteau's Syrup of Iron is specially designed for children. Chalybeate medication, by means of **Rabuteau's Iron,** is the most economical and the most rational known to therapeutics.

No constipation, no diarrhœa, complete assimilation.

Take only the GENUINE IRON OF RABUTEAU of

CLIN & CO., Paris.

SOLUTION OF THE SALICYLATE OF SODA OF DOCTOR CLIN.

Laureate of the Paris Faculty of Medicine (MONTYON PRIZE).

Dr. Clin's Solution, always identical in its composition, and of an agreeable taste, permits the easy administration of *pure Salicylate of Soda*, and the variation of the dose in accordance with the indications presented.

"The *Salicylate of Soda* used by **Clin** is of perfect purity, "and is prepared with the greatest care; it is a medicament "in which we may have every confidence."

—*Paris Society of Medicine, Meeting of Feb. 8th, 1879.*

Clin's Solution, very exactly mixed, contains: 2 grammes of *Salicylate of Soda* per tablespoonful, 50 centigrammes of *Salicylate of Soda* per teaspoonful.

Paris—CLIN & CO.—Paris

PILLS OF DR. MOUSSETTE.

The **Moussette Pills** of aconitine and quinium, calm or cure *Gastralgia, Hemicrania, Headache, Sciatica*, and the most obstinate Neuralgias.

"The sedative action exerted by the **Moussette Pills** "upon the apparatus of the sanguineous circulation by the "intermediation of the vaso-motor nerves, indicates their "use in *neuralgias of the trigemini nerves*, (fifth pair), *con-* "*gestive neuralgias*, and *painful and inflammatory Rheumatismal* "*affections.*"

"Aconitine produces marvelous effects in the treatment "of *facial neuralgias* when they are not symptomatic of "intracranial tumor."—*Society of Biology of Paris, Meeting* "*of the 28th February, 1880.*

Dose—Take 3 to 6 pills during the twenty-four hours.

ACCEPT ONLY THE GENUINE MOUSSETTE PILLS OF

CLIN & CO.,—Paris.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the three Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared Compound Extract of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

Mr. Laroche, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, Anæmia, Chlorosis, Intestinal Hæmorrhage, Castralgia, Exhaustion, Etc., Etc.

PARIS.—22 RUE DROUOT.—PARIS.

Prof. Loisette's MEMORY

DISCOVERY AND TRAINING METHOD

In spite of adulterated imitations which miss the theory, and practical results of the Original, in spite of the grossest misrepresentations by envious would-be competitors, and in spite of "base attempts to rob" him of the fruit of his labors, (all of which demonstrate the undoubted superiority and popularity of his teaching), Prof. Loisette's Art of Never Forgetting is recognized to-day in both Hemispheres as marking an Epoch in Memory Culture. His Prospectus (sent post free) gives opinions of people in all parts of the globe who have actually studied his System by correspondence, showing that his System is *used only while being studied, not afterwards;* that *any book can be learned in a single reading, mind-wandering cured, &c.* For Prospectus, Terms and Testimonials address

Prof. A. LOISETTE, 237 Fifth Avenue, N.Y

The 153d Semi-Annual Course of Instruction on Practical Obstetrics, at the Phila. Lying-in Charity's School of Practical Obstetrics will Begin Monday, April 7th, 1890.

The course of Instruction will embrace the same features that have made it so popular in the last few years. There is an abundance of material, and every Student will receive Instruction at the bedside of the LIVING WOMAN, in ACTIVE labor. For application for membership in the class (which is limited) apply to Dr. Charles Meigs Wilson, Surgeon in charge, Phila. Lying-in Charity, S. W. Cor. 11th & Cherry Sts., Phila.

A limited number of advanced or post-graduate Students will be taken for Instruction on Practical Gynecology. All hours will be arranged so as not to interfere with the work at the various Colleges. The Instruction and opportunities of the Lying-in Charity are free to Dr. Wilson's Office Students.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

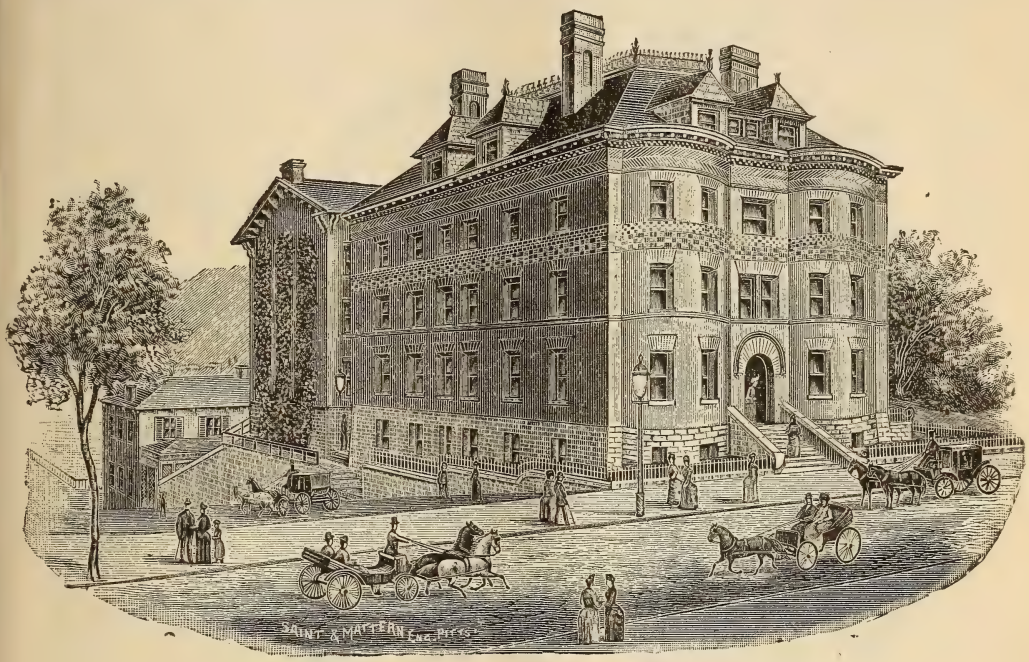
DR. R. S. SUTTON'S

Sanatorium for Diseases of Women.



Seventh Year Opens September 1, 1889.

ALLEGHENY CITY, PA.

This Institution is located on high ground, and overlooks the Allegheny, Monongahela and Ohio rivers; it commands a view of the city of Pittsburgh, and its picturesque surroundings. The building is large and beautiful, it is provided with every modern convenience, the halls are heated by steam, the rooms are commodious, well lighted and ventilated, and heated by open grates. The house is provided with a private parlor and reading-room for patients. The dining-room is large, handsomely finished, and furnished with small tables, securing privacy at meals for those who do not care to have meals served in their own rooms. Patients can be as secluded, should they desire it, as in a well appointed hotel. Each patient is examined by Dr. Sutton, and receives his daily personal attention, while Dr. J. H. Williamson, a physician of ample hospital experience, resides in the Institution, and has, under Dr. Sutton, the immediate care of the patients. The Institution accommodates 25 patients, and is equal in comfort to the best hotels.

Electricity, baths, douches, massage, local treatment, general medication and surgical operations are resorted to according to the requirements of each patient.

For further information address the Matron

MISS KENNEDY,

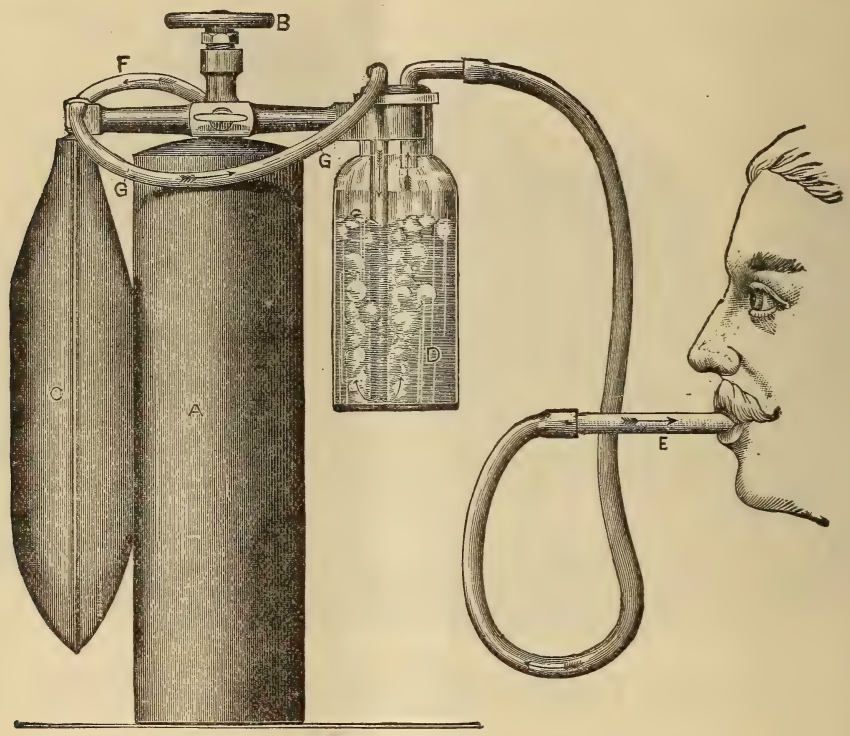
INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request:

Geo Hamlin Prest. Chas Roome Parmele Treas.

GENTLEMEN:

The Case of your wines sent me for analysis by Dr. A. L. Hummel, of the "Annals of Hygiene," containing specimens of your La Rosa Zinfandel, Mataro, Riesling, Royal Tokay, and Royal Grape Brandy, has been duly received.

I have examined them for the common contaminants of wine; to wit: Sulphurous acid and sulphites, salicylic acid, fuchsin, lead salts, etc., none of which I found present therein.

I have also determined their alcoholic strength, extractives, and ashes, and found them to correspond strictly in this respect with the standard of pure and natural wines, which cannot be said of many of the imported wines.

As a native of a wine-producing country, I consider myself somewhat of a judge of wines, and regard your products as comparing more than favorably with most of the wines from abroad which are sold at higher prices, so much so that I enclose within my order for fifty bottles of La Rosa Zinfandel, which I expect to use hereafter exclusively at my table.

Very Respectfully,

L. WOLFF, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

Apollinaris

"THE QUEEN OF TABLE WATERS."

The filling at the Apollinaris Spring (Rhenish Prussia), amounted to

11,894,000 BOTTLES IN **1887,**
12,720,000 BOTTLES IN **1888** AND
15,822,000 BOTTLES IN **1889.**

"The annual consumption of this favorite beverage affords a striking proof of the widespread demand which exists for table water of absolute purity, and it is satisfactory to find that, wherever one travels, in either hemisphere, it is to be met with; it is ubiquitous, and should be known as the cosmopolitan table water. 'Quod ab omnibus, quod ubique.'"—BRITISH MEDICAL JOURNAL.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

THE VALUE OF NUTRITION IN DISEASE.

All physicians who have ever used Murdock's Liquid Food and Suppositories recognize their value over all other foods, in breaking up disease and building up the patients after disease, preventing a relapse, **as the same results are obtained as in surgery.** Its value in surgical cases we illustrate by the records of the different cities and of Murdock's Free Surgical Hospital for Women, which is the largest in the United States. It contains 114 beds, every bed free, including operation, the operations ranging from 1000 to 1200 yearly, representing 90 of the worst classes known in surgery. Among these cases we have had **Cancer of uterus** (*Kolpo-hysterectomy*), 13; **Salpingitis** (*Tait's operation*), 31; **Fibroid of uterus** (*abdominal hysterectomy*), 19; **Ventral operation, hernia,** (*abdominal section*), 12; **Cancer of bowel** (*incision*), 2; **Parovarian cyst, 6; Papillomatous cyst** (*extirpation*), 4; **Tubercular peritonitis** (*incision*), 1; **Ovarian cystoma 27; Nymphomania** (*Battey*), 1; **Exploratory abdominal incisions, 12; Fibroid with abdominal abscess** (*Hegar*), 2; **Hysterorraphy, 2; Dermoid cyst, 3; Cirrhotic ovaries,** (*Battey*), 4; **Fibroid uterus** (*Hegar*), 6; **Hystero-epilepsy** (*Battey*), 1; **Haemato-Salpinx** (*Tait*), 5; **Rupture of intestine into vagina, 1; Dislocated kidney, 2; Fibroid tumor abdominal wall, 1; Resection of intestine** (*Senn*), 1; **Ruptured perineum, 294.** Patients are in the Hospital 8 days before and 26 days after operation, on an average.

In Boston, last year, 42 deaths were from Cancer in the Breast. In Murdock's Hospital, 35 such cases were operated on without a death, the patients remaining in the Hospital, on an average, 18 days.

Mortality in Boston,	. . . . .	25.60	per 1000.
" of Women in Boston,	. . . . .	29,00	" "
" in **Murdock's Free Surgical Hospital,**	.	**5.00**	" "
" New York,	. . . . .	26.32	" "
" Philadelphia,	. . . . .	20.00	" "
" Chicago,	. . . . .	20.90	" "
" St. Louis,	. . . . .	20.49	" "

showing our mortality is only one-sixth as great as of those in health. As good results were obtained in our General Hospital, which we kept open 27 months, **thus showing the value of nutrition as found in Murdock's Liquid Food, and so recognized by the British and American Medical Associations,** before which essays were read and discussed, and it is the only Raw food preparation on which essays were ever read.

Physicians are invited to visit our Hospitals and Works, also to send in patients and to be present at the operations. For any physician who has not used our Liquid Food (and Suppositories for adults and infants), we will deliver free samples to any express company in Boston.

When babies do not thrive, never change their food, but add five or more drops at each feeding of Murdock's Liquid Food, and their lost or needed vitality will be restored in less than thirty days. It is invaluable when weaning babies or when teething. If mothers will take one teaspoonful to a tablespoonful before each meal and on retiring, they will receive as much benefit as the baby.

Murdock Liquid Food Co., Boston.

GARDNER'S

SYRUP OF HYDRIODIC ACID,

Introduced in 1878 by R. W. GARDNER.

The Reputation which Hydriodic Acid has Attained During the past Eleven Years was Won by this Preparation.

Numerous Imitations prepared differently, and weaker in Iodine, are offered, from the use of which the same therapeutic effects cannot be obtained.

Caution.—Use no Syrup of Hydriodic Acid which has turned red. This shows decomposition and free Iodine. In this state it acts as an irritant and fails to produce desirable results.

Unprincipled apothecaries substitute imitations when Gardner's Syrup is prescribed, and physicians, failing to get desirable and promised results, attribute the fault, unjustly, to Gardner's Syrup.

THERAPEUTIC INDICATIONS.

Hay Fever; Rose Cold; Poisoning by Lead, Mercury or Arsenic; Acute and Chronic Rheumatism; Asthma; Chronic Bronchitis; Catarrh; Congestion of Lungs in Children; Adenitis; Eczema; Lupus; Chronic Malarial Poisoning; Lumbago; Acute Pneumonia; Psoriasis; Scrofulous Diseases; Goitre; Enlarged Glands; Cold Abscesses; Indolent Sores; Excessive Fat; Fatty Degeneration of the Heart; to absorb non-malignant Tumors; and in the latter stages of Syphilis; Syphilitic Phthisis.

Details of treatment furnished physicians upon application to undersigned without charge.

Gardner's Chemically Pure Syrups of Hypophosphites.

Embracing the separate Syrups of Lime, of Soda, of Iron, of Potassa, of Manganese, and an Elixir of the Quinia Salt; enabling physicians to accurately follow Dr. Churchill's method, by which thousands of authenticated cases of Phthisis have been cured. The only salts, however, used by Churchill in Phthisis are those of Lime, of Soda, and of Quinia, and always separately according to indications,—never combined.

The reason for the use of single Salts is because of antagonistic action of the different bases, injurious and pathological action of Iron, Potassa, Manganese, etc., in this disease.

These facts have been demonstrated by thirty years' clinical experience in the treatment of this disease exclusively, by Dr. Churchill, who was the first to apply these remedies in Medical practice. Modified doses are also required in this disease; seven grains during twenty-four hours being the maximum dose in cases of Phthisis, because of increased susceptibility of the patient to their action, the danger of producing toxic symptoms (as hemorrhage, rapid softening of tubercular deposit, etc.), and the necessity that time be allowed the various functions to recuperate simultaneously; over-stimulation, by pushing the remedy, resulting in crisis and disaster.

A pamphlet of sixty-four pages, devoted to a full explanation of these details and others, such as contra-indicated remedies, indications for the use of each hypophosphite, reasons for the use of absolutely pure Salts, protected in Syrup from oxidation, etc., mailed to physicians without charge upon application to

R. W. GARDNER, 158 William St., N. Y. City.

W. H. SCHIEFFELIN & CO., Sole Wholesale Agents, New York.

CELERINA

NERVE TONIC, STIMULANT AND ANTISPASMODIC.

FORMULA.—Every Fluid Drachm represents FIVE grains EACH—Celery, Coca, Kola, Viburnum and Aromatics.

INDICATIONS.—Loss of Nerve-Power (so usual with Lawyers, Preachers, Writers and Business Men), Impotency, Spermatorrhea, Nervous Headache, Neuralgia, Paralysis, Hysteria, Opium Habit, Inebriety, Dyspepsia, and ALL LANGUID conditions of the System.

Indispensable to restore a patient after alcoholic excess.

DOSE.—One or two Teaspoonfuls three or more times a day, as directed by the Physician.

LIQUID IRON-RIO

Palatable and easily assimilated. Does not produce Nausea, nor irritate the Stomach. Does not Cause Headache, nor Constipate. Does not Stain the Teeth. It is so Acceptable to the Stomach that its Use is Admissible when all other forms of Iron would be rejected. Being so Readily Assimilable, it only requires a small Dose.

Each Fluid Drachm contains ONE GRAIN of Iron in a Pleasant and Digestible Form.

DOSE.—One or more Teaspoonfuls as indicated, during or after meals.

S. H. KENNEDY'S

CONCENTRATED EXTRACT OF

PINUS CANADENSIS

DARK. A NON-ALCOHOLIC LIQUID. WHITE.

A MOST VALUABLE NON-IRRITATING MUCOUS ASTRINGENT.

INDICATIONS.—Albuminuria, Diarrhea, Dysentery, Night-Sweats, Hemorrhages, Profuse Expectoration, Catarrh, Sore Throat, Leucorrhea, and other Vaginal Diseases, Piles, Sores, Ulcers, Burns, Scalds, Gonorrhea, Gleet, Etc.

When Used as an Injection, to Avoid Staining of Linen, the WHITE Pinus should be used.

RECOMMENDED BY PROMINENT EUROPEAN AND AMERICAN PHYSICIANS.

RIO CHEMICAL CO., St. Louis, Mo., U. S. A.

LONDON. PARIS. CALCUTTA. MONTREAL.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

ESTABLISHED 1855.

DRS. STRONG'S SANITARIUM,

SARATOGA SPRINGS, NEW YORK,

Receives persons recommended to it by their home physicians for Treatment, Change, Rest or Recreation, and places them under well-regulated hygienic conditions so helpful in the treatment of chronic invalids or the overtaxed.

For Treatment: In addition to the ordinary remedial agents, it employs Turkish, Russian, Roman, Sulphur, Electro-Thermal, the French Douche (Charcot's), and all Hydropathic Baths; Vacuum Treatment, Swedish Movements Massage, Pneumatic Cabinet, Inhalations of Medicated, Compressed, and Rarefied Air, Electricity in various forms, Thermo-Cautery, Calisthenics, and Saratoga Waters, under the direction of a staff of educated physicians.

For Change: This Institution is located in a phenomenally dry, tonic, and quiet atmosphere, in the lower arc of the Adirondack Zone, and within the "Snow Belt."

For Rest: The Institution offers a well-regulated, quiet home, heated by steam and thoroughly ventilated, with cheering influences and avoiding the depressing atmosphere of invalidism.

For Recreation: To prevent introspection, are household sports at all seasons of the year, and in Winter, tobogganning, elegant sleighing etc.; in Summer, croquet, lawn-tennis, etc.

Private professional references furnished upon application. Physicians are invited to inspect the Institution at their convenience. A liberal discount to physicians and their families.

For further information, address,

DRS. S. S. & S. E. STRONG.

THE OLD STYLE discarded on account of pulling apart, while the elastic is still in good condition.

THE "MASTER" SURGICAL ELASTIC STOCKINGS

FOR VARICOSE VEINS, WEAK AND SWOLLEN JOINTS, DROPSY OF THE LIMBS, SPRAINS, etc.

PROVIDED WITH

THE PATENT NON-ELASTIC STAYS AND ADJUSTING LOOPS,

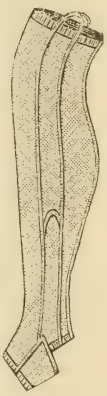
By the aid of which they can be drawn on easily, like pulling on a boot. They will last much longer than the old style, as the stays prevent them from being torn apart in drawing them on.

ALL KINDS AND SIZES IN THREAD OR SILK ELASTIC. Made under D. Master's Patents, Nov. 29, 1881, March 21, 1882. Send for descriptive circular and price-list to

POMEROY TRUSS CO.,

785 Broadway, New York.

DANIEL POMEROY, Pres. CHARLES R. DEAN, Sec.



THE NEW STYLE cannot pull apart and consequently lasts until worn out.

ONEITA

The perfection of table waters, with mineral properties unsurpassed in the treatment of Dyspepsia, Kidney and Liver troubles, Gout, Rheumatism, etc. The analysis of the spring shows a combination of mineral virtues unequaled in any other water. The water has been before the public but a short time, yet in that time has won public favor to a marked degree. Send for analysis of C. F. Chandler, Ph. D.
